

# DISCRETE-TIME APPROXIMATIONS OF STOCHASTIC DELAY EQUATIONS: THE MILSTEIN SCHEME<sup>†</sup>

YAOZHONG HU\*, SALAH-ELDIN A. MOHAMMED<sup>‡</sup> AND FENG YAN

ABSTRACT. In this paper, we develop a strong Milstein approximation scheme for solving stochastic delay differential equations (SDDE's). The scheme has convergence order 1. In order to establish the scheme, we prove an infinite-dimensional Itô formula for “tame” functions acting on the segment process of the solution of an SDDE. It is interesting to note that the presence of the memory in the SDDE requires the use of the Malliavin calculus and the anticipating stochastic analysis of Nualart and Pardoux. Given the *non-anticipating* nature of the SDDE, the use of anticipating calculus methods in the context of strong approximation schemes appears to be novel.

## 1. Introduction.

Discrete-time strong approximation schemes for stochastic ordinary differential equations (SODE's) are well developed. For an extensive study of these numerical schemes, one may refer to ([18]), ([19]), and ([21], Chapters 5 and 6). Some basic ideas of strong and weak orders of convergence are illustrated in ([13]).

If the rate of change of a physical system depends only on its *present state* and some noisy input, then the system can often be described by a stochastic *ordinary* differential equation (SODE). However, in many physical situations the rate of change of the state depends not only on the present but also on the past states of the system. In such cases, stochastic delay differential equations (SDDE's) or stochastic functional differential

*Running head*: Discrete-time approximations of SDDE's

equations (SFDE's) provide important tools to describe and analyze these systems. For various aspects of the qualitative theory of SFDE's the reader may refer to ([22], [23]) and the references therein.

SDDE's and SFDE's arising in many applications cannot be solved explicitly. Hence, one needs to develop effective numerical techniques for such systems. Depending on the particular physical model, it may be necessary to design strong  $L^p$  (or almost sure) numerical schemes for *pathwise* solutions of the underlying SFDE. Strong approximation schemes for SFDE's may be used to simulate directly the a.s. stochastic dynamics of their trajectories or their random attractors. SFDE's are used to model population growth with incubation/gestation period ([23]). In such models, one is often interested in estimating the actual population rather than its distribution, and hence the need for strong approximation schemes.

In this article, we will not consider the order of convergence of *weak* numerical schemes, although such schemes are useful for some applications of SODE's (see [13], [18] and the references therein). In this connection, it is important to note that stochastic systems with memory *do not correspond to deterministic PDE's* (in finitely many space variables) ([22], [23]). Typically, a stochastic system with memory corresponds to an *infinite-dimensional* Feller diffusion whose principal coefficient degenerates on a hypersurface with *finite-codimension* ([22], Chapter IV, Theorem 3.2, [23], Theorem II.3 ). This aspect of SFDE's is in sharp contrast with the theory of SODE's where the latter theory has traditional ties to diffusions in Euclidean space. In a sense, the numerics of stochastic systems with memory resemble those of SPDE's in one space dimension.

A strong Cauchy-Maruyama scheme for a class of SFDE's with continuous memory, in the context of the Delfour-Mitter state space  $\mathbf{R}^m \times L^2([-\tau, 0], \mathbf{R}^m)$ , was developed by T.A. Ahmed, S.A. Elsanousi and S.-E. A. Mohammed ([1]). See also [22], p. 227, [15] and [4]. As in the case of stochastic ordinary differential equations (SODE's), the Cauchy-Maruyama scheme for SFDE's has order of convergence  $\frac{1}{2}$  ([22], p. 227, [15], [4]).

In sections 2-5, we establish the *strong Milstein scheme* for SDDE's with several delays. This scheme has a higher strong order of convergence 1 when compared with the Euler scheme which, as indicated above, has the strong order of convergence 0.5. Furthermore, when simulating the whole solution path  $\{X(t), t \in [0, a]\}$ , the Milstein schemes for SDDE's and SODE's have the same complexity, even when one accounts for the simulation of the iterated stochastic integrals in the scheme. (See Appendix B and Remark B.1). Although the solution of the SDDE is *adapted* to the (lagged) filtration of the driving noise, methods from *anticipating* stochastic analysis and the Malliavin calculus are necessary in order to derive an Itô formula for the segment of the solution process. The Itô formula is essential for the development of the Milstein scheme.

In order to put our analysis in proper perspective, we highlight its essential features: (a) The dynamics and the coefficients of the SDDE's are adapted, in fact driven by Itô integrals, (b) the formulation and implementation of the Milstein scheme do not require anticipating calculus ideas, (c) the proof of convergence of the Milstein scheme as well as the Itô formula employ anticipating calculus techniques, (d) anticipating calculus methods are used in the context of *strong* approximation schemes rather than weak ones (where the Feynman-Kac formula lends itself naturally to the use of Malliavin calculus methods), (e) the application of anticipating calculus methods seems unavoidable as soon as one seeks higher-order approximation results.

In an essentially non-adapted setting, anticipating calculus methods have been used by Pardoux and Protter to study stochastic Volterra equations with anticipating coefficients. See ([26]) and the references therein. Cf. also [7].

In order to describe our set-up, we need the following notation.

Let  $\mathbf{R}^m$  be  $m$ -dimensional Euclidean space with the Euclidean norm  $|x| := \sqrt{x_1^2 + \cdots + x_m^2}$ ,  $x = (x_1, \cdots, x_m) \in \mathbf{R}^m$ . Denote  $T := [0, a]$ ,  $J := [-\tau, 0]$ ,  $C := C(J; \mathbf{R}^m)$ , where  $m$  is a positive integer,  $\tau > 0$  is a fixed delay (as in (1.6) below) and  $a > 0$ . Furnish  $C$  with the supremum norm  $\|\eta\|_C := \sup_{-\tau \leq s \leq 0} |\eta(s)|$  for all  $\eta \in C$ .

Define the projection  $\Pi : C \rightarrow \mathbf{R}^{mk}$  associated with  $s_1, \dots, s_k \in [-\tau, 0]$  by

$$(1.1) \quad \Pi(\eta) := (\eta(s_1), \dots, \eta(s_k)) \in \mathbf{R}^{mk}$$

for all  $\eta \in C$ .

**Definition 1.1.**

A function  $\Phi \in C(T \times C(J; \mathbf{R}^m); \mathbf{R})$  is *tame* if there exist  $\phi \in C(T \times \mathbf{R}^{mk}, \mathbf{R})$  and a projection  $\Pi : C \rightarrow \mathbf{R}^{mk}$  such that

$$(1.2) \quad \Phi(t, \eta) = \phi(t, \Pi(\eta)).$$

for all  $t \in T$  and  $\eta \in C$ .

Let  $(\Omega, \mathcal{F}, P)$  be a probability space. For any continuous  $m$ -dimensional process  $X : [-\tau, a] \times \Omega \rightarrow \mathbf{R}^m$ , define the segment process  $X_t, t \in [0, a]$ , by

$$(1.3) \quad X_t(u) = X(t + u), \quad t \in [0, a], \quad u \in [-\tau, 0].$$

Observe that  $\{X_t\}$  may be considered as a  $C$ -valued or  $L^2(J; \mathbf{R}^m)$ -valued process.

*It is important that one should distinguish between the finite-dimensional current state  $X(t)$  and the infinite-dimensional segment  $X_t, t \in [0, a]$ .*

Assume that  $g : T \times \mathbf{R}^{mk_1} \rightarrow L(\mathbf{R}^d; \mathbf{R}^m)$  and  $h : T \times \mathbf{R}^{mk_2} \rightarrow \mathbf{R}^m$  satisfy the following *Lipschitz condition*:

$$(1.4) \quad |g(t, x) - g(t, y)| \leq L|x - y|, \quad |h(t, z) - h(t, w)| \leq L|z - w|$$

for all  $t \in T, x, y \in \mathbf{R}^{mk_1}$  and  $z, w \in \mathbf{R}^{mk_2}$ , where  $L > 0$  is a constant, together with the *boundedness condition*:

$$(1.5) \quad \sup_{0 \leq t \leq a} [|g(t, 0)| + |h(t, 0)|] < \infty.$$

Let  $\Pi_1$  and  $\Pi_2$  be two projections associated with two sets of points  $s_{1,1}, \dots, s_{1,k_1} \in [-\tau, 0]$  and  $s_{2,1}, \dots, s_{2,k_2} \in [-\tau, 0]$ , respectively. Suppose  $\{W(t) := (W^1(t), \dots, W^d(t)) :$

$t \geq 0\}$  is a  $d$ -dimensional standard Brownian motion defined on a filtered probability space  $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, P)$  satisfying the usual conditions. Let  $\eta : \Omega \rightarrow C([-\tau, 0]; \mathbf{R}^m)$  be an  $\mathcal{F}_0$ -measurable initial process.

We will first consider the following class of Itô SDDE's:

$$(1.6) \quad X(t) = \begin{cases} \eta(0) + \int_0^t g(s, \Pi_1(X_s)) dW(s) + \int_0^t h(s, \Pi_2(X_s)) ds, & t \geq 0, \\ \eta(t), & -\tau \leq t < 0. \end{cases}$$

Under conditions (1.4) and (1.5), the SDDE (1.6) has a unique strong solution (c.f. [22], Theorem II.2.1, p. 36; and Theorem V.4.3, pp. 151-152). To see this, let  $G(t, \eta) := g(t, \Pi_1(\eta))$  and  $H(t, \eta) := h(t, \Pi_2(\eta))$  for  $t \in [0, a], \eta \in C$ . It is easy to check that  $G$  and  $H$  satisfy the Lipschitz and local boundedness conditions (with respect to the supremum norm on  $C$ ) of Theorems II.2.1 and V.4.3 of [22]. Therefore, for each  $p \geq 1$ , there exists a constant  $C = C(p, L, a) > 0$  such that

$$(1.7) \quad E\|X_t\|_C^{2p} \leq C(1 + E\|\eta\|_C^{2p})$$

for all  $\eta \in C, t \in [0, a]$ .

For any integers  $n, l \geq 1$ , let  $\pi : t_{-l} < t_{-l+1} < \dots < 0 = t_0 < t_1 < t_2 < \dots < t_n$  be a partition of  $[-\tau, a]$ . Denote by  $|\pi| := \max_{-l \leq i \leq n-1} (t_{i+1} - t_i)$ , the mesh of  $\pi$ . We now introduce the following Milstein scheme for the SDDE (1.6):

$$(1.8) \quad \begin{aligned} X^{i, \pi}(t) &= X^{i, \pi}(t_k) + h^i(t_k, \Pi_2(X_{t_k}^\pi))(t - t_k) + g^{ij}(t_k, \Pi_1(X_{t_k}^\pi))(W^j(t) - W^j(t_k)) \\ &\quad + \frac{\partial g^{ij}}{\partial x_{i_1 j_1}}(t_k, \Pi_1(X_{t_k}^\pi)) u^{i_1 j_1, \pi}(t_k + s_{1, j_1}) I_{j, j_1}(t_k + s_{1, j_1}, t + s_{1, j_1}; s_{1, j_1}), \end{aligned}$$

for  $t_k < t \leq t_{k+1}$ , and

$$X^\pi(t) := \eta^\pi(t), \quad t \in [-\tau, 0]$$

where

$$(1.9) \quad u^{i_1 j_1, \pi}(t) := \begin{cases} g^{i_1 j_1}(t, \Pi_1(X_t^\pi)), & t \geq 0, \\ 0, & -\tau \leq t < 0, \end{cases}$$

$$(1.10) \quad I_{j,j_1}(t_0 + s, t + s; s) := \int_{t_0}^t \int_{t_0+s}^{t_1+s} \circ dW^j(t_2) \circ dW^{j_1}(t_1), \quad t \geq t_0 \geq 0, s \in [-\tau, 0],$$

and the starting path  $\eta^\pi \in C(J, \mathbf{R}^m)$  is prescribed (e.g. a piece-wise linear approximation of  $\eta$  using the partition points  $\{t_{-l}, \dots, t_0\}$ ). In (1.8),  $X^i$ ,  $h^i$  and  $g^{ij}$  denote coordinate representations of  $X$ ,  $h$  and  $g$  with respect to standard bases in the underlying Euclidean spaces, and the Einstein summation convention is used for repeated indices.

In order to establish strong convergence of the above Milstein scheme for the SDDE (1.6), it turns out -surprisingly-that one requires the use of *anticipating* calculus techniques developed by Nualart and Pardoux ([24]). In particular, one needs to develop an infinite-dimensional Itô formula for “tame” functions acting on the segment  $X_t$  of the solution  $X$  of (1.6). Such an Itô formula is given in Section 2, Theorem 2.3. The formula is proved via anticipating calculus methods ([24]). To understand the *need* for *anticipating* calculus in such an *intrinsically adapted* setting, it is instructive to look at the following simple one-dimensional SDDE:

$$\begin{aligned} dX(t) &= g(X(t-1), X(t)) dW(t), \quad t \geq 0 \\ X(t) &= W(t), \quad -1 \leq t < 0. \end{aligned}$$

where  $g : \mathbf{R}^2 \rightarrow \mathbf{R}$  is a smooth function and  $W(t), t \geq -1$ , is one-dimensional Brownian motion. For a second-order scheme, we formally seek a stochastic differential of the coefficient  $g(X(t-1), X(t))$  on the right hand side of the above SDDE. For  $t \in (0, 1]$ , this gives formally:

$$\begin{aligned} &d\{g(X(t-1), X(t))\} \\ &= d\{g(W(t-1), X(t))\} \\ &= \frac{\partial g}{\partial x}(W(t-1), X(t)) dW(t-1) + \frac{\partial g}{\partial y}(W(t-1), X(t)) g(X(t-1), X(t)) dW(t) \\ &\quad + \text{second-order terms.} \end{aligned}$$

Note that although the coefficient  $g(X(t-1), X(t))$  is  $\mathcal{F}_t$ -measurable, the first term  $\frac{\partial g}{\partial x}(W(t-1), X(t)) dW(t-1)$  in the right hand side of the last equality is an *anticipating* differential. Furthermore, it appears that the  $(\mathcal{F}_t)_{0 \leq t \leq 1}$ -adapted process  $[0, 1] \ni t \rightarrow (X(t-1), X(t)) \in \mathbf{R}^2$  is not a semimartingale with respect to any natural filtration. In addition to this difficulty, the components  $X(t-1)$  and  $X(t)$  are not independent, so the existing anticipating versions of Itô's formula do not apply (cf. [2], [3] and [24]); hence the need for a new Itô formula for tame functions in order to justify the above computation. In the next section (Theorem 2.3), we establish such a formula.

Using the above-mentioned Itô formula and appropriate estimates on the weak Cameron-Martin derivatives of  $X$ , it is shown in section 5 (Theorem 5.2) that, under suitable regularity conditions on the coefficients of (1.6), one gets the following global error estimate for the Milstein approximations

$$(1.11) \quad E \sup_{0 \leq t \leq a} \|X_t^\pi - X_t\|_C^q \leq C(q) |\pi|^q$$

for any  $q \geq 1$ . This says that the Milstein scheme has strong order of convergence 1.

## 2. Itô's formula for "tame" functions..

In order to derive higher order numerical schemes for SDDE's, we shall first prove an Itô formula for "tame" functions on  $C(J, \mathbf{R}^m)$  (Definition 1.1).

Suppose that  $W(t) := (W^1(t), \dots, W^d(t))$ ,  $t \geq 0$ , is a  $d$ -dimensional standard Brownian motion on a filtered probability space  $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, P)$ . Denote by  $D = (D_1, \dots, D_d)$  the Malliavin differentiation operator associated with  $\{W(t) : t \geq 0\}$ . Assume

$$(2.1) \quad X(t) = \begin{cases} \eta(0) + \int_0^t u(s) dW(s) + \int_0^t v(s) ds, & t > 0, \\ \eta(t), & -\tau \leq t \leq 0, \end{cases}$$

where  $\eta$  belongs to  $C$  and is of bounded variation,  $u = (u^1, \dots, u^m)^T$ ,  $u^i \in \mathbb{L}_{d,loc}^{2,4}$ ,  $v = (v^1, \dots, v^m)^T$ , and  $v^i \in \mathbb{L}_{loc}^{1,4}$ . One can refer to ([25], pp. 61, 151, 161) for the definition

of  $\mathbb{L}_d^{k,p}$ . Note that the processes  $u$  and  $v$  may not be adapted to the Brownian filtration  $(\mathcal{F}_t)_{t \geq 0}$ . For convenience, we define  $u(t) = 0$  for  $t < 0$  or  $t > a$ ,

$$v(t) = \begin{cases} 0, & t > a \\ \eta'(t), & -\tau \leq t \leq 0. \end{cases}$$

We also set  $W(t) = 0$  if  $t < 0$  or  $t > a$ , and denote

$$(2.2) \quad U(t) := \int_0^t u(s) dW(s) \text{ and } V(t) := \begin{cases} \eta(0) + \int_0^t v(s) ds, & t > 0 \\ \eta(t), & -\tau \leq t \leq 0. \end{cases}$$

If  $u \in \mathbb{L}_{loc}^{2,p}$  for some  $p > 4$ , then the indefinite Skorohod integral  $\int_0^t u(s) dW(s)$  has a continuous version. Hence we may assume that the process  $X(t), t \geq -\tau$ , is sample continuous.

Let  $T = [0, a]$ ,  $J = [-\tau, 0]$ ,  $C = C(J; \mathbf{R}^m)$  be as before, and let  $\Pi$  be the projection associated with  $s_1, \dots, s_k \in J$ . Although there is a multidimensional Itô formula for  $\phi(t, X(t))$  ([2], [3] and [24]), we can not apply it to  $\phi(t, \Pi(X_t))$  because  $\Pi(U_t)$  is of the form

$$(2.3) \quad \left( \int_0^t u(s + s_1) dW(s + s_1), \dots, \int_0^t u(s + s_k) dW(s + s_k) \right), \quad t > 0,$$

and the components of the  $dk$ -dimensional process  $(W(t + s_1), \dots, W(t + s_k))$  are not independent. However, the ideas in Nualart and Pardoux ([24], Section 6; [25], p. 161) can be used to derive an Itô formula for  $\phi(t, \Pi(X_t))$ . Cf. [32] for further details.

We denote by

$$(2.4) \quad \delta_{ij} = \begin{cases} 1, & i = j, \\ 0, & i \neq j, \end{cases}$$

the Kronecker delta.

For any process  $X(t), t \in [-\tau, a]$ , denote its (delayed) increments by

$$(2.5) \quad \Delta_{li} X := X(t_l + s_i) - X(t_{l-1} + s_i), \quad 1 \leq l \leq n, i = 1, 2, \dots, k.$$

Assume that  $\phi \in C^{1,2}(T \times \mathbf{R}^{mk})$ , and write

$$(2.6) \quad \phi(t, \vec{x}) := \phi(t, \vec{x}_1, \dots, \vec{x}_m)$$

where  $\vec{x} := (\vec{x}_1, \dots, \vec{x}_m)$ ,  $\vec{x}_i := (x_{i1}, \dots, x_{ik}) \in \mathbf{R}^k$ ,  $1 \leq i \leq m$ .

We now state an Itô's formula for "tame" functions.

**Theorem 2.3.**

Assume that  $X$  is a continuous process defined by (2.1), where  $\eta : J \rightarrow \mathbf{R}^m$  is of bounded variation,  $u = (u^1, \dots, u^m)^T$ ,  $u^i \in \mathbb{L}_{d,loc}^{2,4}$ ,  $v = (v^1, \dots, v^m)^T$ , and  $v^i \in \mathbb{L}_{loc}^{1,4}$ . Suppose  $\phi \in C^{1,2}(T \times \mathbf{R}^{mk}, \mathbf{R})$ . Then

$$(2.7) \quad \begin{aligned} & \phi(t, \Pi(X_t)) - \phi(0, \Pi(X_0)) \\ &= \int_0^t \frac{\partial \phi}{\partial s}(s, \Pi(X_s)) ds + \int_0^t \frac{\partial \phi}{\partial \vec{x}}(s, \Pi(X_s)) d(\Pi(X_s)) \\ & \quad + \frac{1}{2} \sum_{i,j=1}^k \sum_{i_1, j_1=1}^m \int_0^t \frac{\partial^2 \phi}{\partial x_{i_1 i} \partial x_{j_1 j}}(s, \Pi(X_s)) u^{i_1}(s + s_i) D_{s+s_i} X^{j_1}(s + s_j) ds \end{aligned}$$

*Remarks 2.1.*

(i) The Itô formula (2.7) may also be expressed in the form

$$(2.8) \quad \begin{aligned} \phi(t, \Pi(X_t)) - \phi(0, \Pi(X_0)) &= \int_0^t \frac{\partial \phi}{\partial s}(s, \Pi(X_s)) ds + \int_0^t \frac{\partial \phi}{\partial \vec{x}}(s, \Pi(X_s)) d(\Pi(X_s)) \\ & \quad + \frac{1}{2} \sum_{i,j=1}^k \int_0^t Tr \left[ \frac{\partial^2 \phi}{\partial \vec{x}_i \partial \vec{x}_j}(s, \Pi(X_s)) (\Theta_s(s_i, s_j)) \right] ds \end{aligned}$$

where

$$\Theta_s(\alpha, \beta) := \frac{1}{2} \left\{ (u\Lambda)_s X_s(\alpha, \beta) + (u\Lambda)_s X_s(\beta, \alpha) \right\}, \quad \alpha, \beta \in [-\tau, 0],$$

and the two-parameter process  $(u\Lambda)_s X_s : \Omega \times J^2 \rightarrow L(\mathbf{R}^m; \mathbf{R}^m)$  is defined by

$$\begin{aligned} (u\Lambda)_s X_s(\alpha, \beta) &:= I_{\{0 \leq s+\alpha \wedge \beta\}} u(s + \alpha) [u^T(s + \alpha) I_{\{0 \leq s+\alpha \leq s+\beta\}} \\ & \quad + \int_0^{s+\beta} D_{s+\alpha} u(r) dW(r) + \int_0^{s+\beta} D_{s+\alpha} v(r) dr]. \end{aligned}$$

for all  $\alpha, \beta \in [-\tau, 0]$ .

(ii) Suppose  $d = m = 1$ . Let us define a trace operator  $\nabla$ . For  $1 \leq i, j \leq k$ , define

$$(2.9) \quad \nabla_{s_i, s_j}^\pm X(s) := \lim_{\epsilon \downarrow 0} (D_{s+s_i} X(s + s_j + \epsilon) \pm D_{s+s_i} X(s + s_j - \epsilon)) \in \mathbf{R}$$

and  $\nabla_{s_i}^\pm X(s) := (\nabla_{s_i, s_1}^\pm X(s), \dots, \nabla_{s_i, s_k}^\pm X(s)) \in \mathbf{R}^k$ . Then the Itô formula for “tame” functions can be written as

$$(2.10) \quad \begin{aligned} \phi(t, \Pi(X_t)) - \phi(0, \Pi(X_0)) &= \int_0^t \frac{\partial \phi}{\partial s}(s, \Pi(X_s)) ds + \int_0^t \frac{\partial \phi}{\partial \vec{x}}(s, \Pi(X_s)) d\Pi(W_s) \\ &\quad + \frac{1}{2} \sum_{i=1}^k \int_0^t \left\langle \frac{\partial^2 \phi}{\partial x_i^2}(s, \Pi(X_s)) \nabla_{s_i}^+ X(s), \nabla_{s_i}^- X(s) \right\rangle_{\mathbf{R}^d} ds, \end{aligned}$$

a.s. for all  $t \in T$ , where  $\vec{x} := (x_1, \dots, x_k)$  and  $\langle \cdot, \cdot \rangle_{\mathbf{R}^d}$  denotes the Euclidean inner product on  $\mathbf{R}^d$ . Cf. [24], Remark 7.6.

- (iii) The Itô formula (2.7) still holds if the initial path is an  $\mathcal{F}_0$ -measurable process  $\eta : \Omega \rightarrow C$  with a.a. sample paths of bounded variation. A similar remark also holds for Theorem 5.2 of section 5.

For simplicity, we shall prove the Itô formula for the case  $d = m = 1$ . We thus assume in what follows that  $d = m = 1$ .

*Proof of Theorem 2.3.*

For any integer  $n \geq 1$ , let  $\{\pi_n : 0 = t_0 < t_1 < \dots < t_n = a\}$  be a partition of  $[0, a]$ . Then by Taylor’s Theorem, we may write

$$\begin{aligned} \phi(t, \Pi(X_t)) - \phi(0, \Pi(X_0)) &= \sum_{l=1}^n [\phi(t_l, \Pi(X_{t_l})) - \phi(t_{l-1}, \Pi(X_{t_l}))] + [\phi(t_{l-1}, \Pi(X_{t_l})) - \phi(t_{l-1}, \Pi(X_{t_{l-1}}))] \\ &= \sum_{l=1}^n \frac{\partial \phi}{\partial s}(\hat{t}_l, \Pi(X_{t_l})) \Delta t_l + \sum_{l=1}^n \left\{ \sum_{i=1}^k \frac{\partial \phi}{\partial x_i}(t_{l-1}, \Pi(X_{t_{l-1}})) \Delta_{li} X \right. \\ &\quad \left. + \frac{1}{2} \sum_{i,j=1}^k \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(\bar{X}_{t_l})) \Delta_{li} X \Delta_{lj} X \right\}, \quad t \in T, \end{aligned}$$

where

$$\Delta t_l := t_l - t_{l-1}, \bar{X}_{t_l} = X_{t_{l-1}} + \alpha_l (X_{t_l} - X_{t_{l-1}}), \quad \hat{t}_l = t_{l-1} + \gamma_l \Delta t_l$$

for some random variables  $0 \leq \alpha_l, \gamma_l \leq 1$ ,  $l = 1, \dots, n$ . The Itô formula (2.10) will then follow from Proposition 2.5 and Proposition 2.6 below.  $\square$

The rest of this section is devoted to the proofs of Propositions 2.4-2.6.

**Proposition 2.4.**

Suppose that  $W(t)$  is a 1-dimensional Brownian motion. Let  $u \in \mathbb{L}_{loc}^{1,2}$  be such that  $u(t) = 0$  if  $t > a$  or  $t < 0$ . Assume that  $-\tau \leq s_1, s_2 \leq 0$ , and let  $\pi_n : 0 = t_0 < t_1 < \dots < t_n = a$  be a family of partitions of  $T = [0, a]$ , with  $|\pi_n| \rightarrow 0$  as  $n \rightarrow \infty$ . Then

$$(2.11) \quad \lim_{n \rightarrow \infty} \left[ \sum_{l=1}^n \int_{t_{l-1}+s_1}^{t_l+s_1} u(s) dW(s) \right]^2 = \int_0^{a+s_1} u^2(s) ds$$

in probability. If  $s_1 \neq s_2$ , then

$$(2.12) \quad \lim_{n \rightarrow \infty} \sum_{l=1}^n \int_{t_{l-1}+s_1}^{t_l+s_1} u(s) dW(s) \int_{t_{l-1}+s_2}^{t_l+s_2} u(s) dW(s) = 0$$

in probability. Furthermore, if  $u \in \mathbb{L}^{1,2}$ , then the above convergences are in  $L^1(\Omega, \mathbf{R})$ .

*Proof.*

We prove the proposition for  $u \in \mathbb{L}^{1,2}$ . The general case  $u \in \mathbb{L}_{loc}^{1,2}$  follows by a standard localization argument ([25]).

If  $u_i, u_j, v_i, v_j \in \mathbb{L}^{1,2}$  with  $u_i(t) = v_i(t) = 0$  if  $t < 0$  or  $t > a + s_i$  and  $u_j(t) = v_j(t) = 0$  if  $t < 0$  or  $t > a + s_j$ . Set

$$(2.13) \quad \begin{cases} U_i(t) := \int_0^t u_i(s) dW(s) & V_i(t) := \int_0^t v_i(s) dW(s) \\ U_j(t) := \int_0^t u_j(s) dW(s) & V_j(t) := \int_0^t v_j(s) dW(s). \end{cases}$$

Then

$$\begin{aligned}
& E \left| \sum_{l=1}^n \Delta_{l_i} U_i \Delta_{l_j} U_j - \sum_{l=1}^n \Delta_{l_i} V_i \Delta_{l_j} V_j \right| \\
&= E \left| \sum_{l=1}^n \Delta_{l_i} (U_i - V_i) \Delta_{l_j} U_j + \sum_{l=1}^n \Delta_{l_i} V_i \Delta_{l_j} (U_j - V_j) \right| \\
&\leq E \left| \sum_{l=1}^n \Delta_{l_i} (U_i - V_i) \Delta_{l_j} U_j \right| + E \left| \sum_{l=1}^n \Delta_{l_i} V_i \Delta_{l_j} (U_j - V_j) \right| \\
&\leq (E \sum_{l=1}^n |\Delta_{l_i} (U_i - V_i)|^2)^{\frac{1}{2}} (E \sum_{l=1}^n |\Delta_{l_j} (U_j)|^2)^{\frac{1}{2}} \\
&\quad + (E \sum_{l=1}^n |\Delta_{l_i} (V_i)|^2)^{\frac{1}{2}} (E \sum_{l=1}^n |\Delta_{l_j} (U_j - V_j)|^2)^{\frac{1}{2}}.
\end{aligned}$$

By an  $L^p$  estimate of the Skorohod integral ([24], Proposition 3.5; [25], p.158), we have

$$\begin{aligned}
E \sum_{l=1}^n |\Delta_{l_j} U_j|^2 &= E \sum_{l=1}^n \left| \int_{t_{l-1}+s_j}^{t_l+s_j} u_j(s) dW(s) \right|^2 \\
&= E \sum_{l=1}^n \left| \int_0^a I_{(t_{l-1}+s_j, t_l+s_j]}(s) u_j(s) dW(s) \right|^2 \\
&\leq \sum_{l=1}^n \int_0^a I_{(t_{l-1}+s_j, t_l+s_j]}(s) E u_j^2(s) ds \\
&\quad + \sum_{l=1}^n \int_0^a \int_0^a I_{(t_{l-1}+s_j, t_l+s_j]}(s) E (D_t u_j(s))^2 ds dt \\
&= \int_0^a E u_j^2(s) ds + \int_0^a \int_0^a E (D_t u_j(s))^2 ds dt \\
&= \|u_j\|_{1,2}^2.
\end{aligned}$$

Hence we obtain the following inequality

$$(2.14) \quad E \left| \sum_{l=1}^n \Delta_{l_i} U_i \Delta_{l_j} U_j - \sum_{l=1}^n \Delta_{l_i} V_i \Delta_{l_j} V_j \right| \leq \|u_i - v_i\|_{1,2} \|u_j\|_{1,2} + \|v_i\|_{1,2} \|u_j - v_j\|_{1,2}.$$

Since  $\mathbb{L}^{1,2} \cap L^4(\Omega \times [0, a])$  is dense in  $\mathbb{L}^{1,2}$ , it suffices to prove (2.12) for the case  $u \in \mathbb{L}^{1,2} \cap L^4(\Omega \times [0, a])$ . Set

$$(2.15) \quad u_i(t) := \begin{cases} u(t), & 0 \leq t \leq a + s_i \\ 0, & t < 0 \text{ or } t > a + s_i. \end{cases}$$

Define

$$(2.16) \quad u_i^n(t) := \sum_{l=1}^n \frac{I_{(t_{l-1}+s_i, t_l+s_i]}(t)}{t_l - t_{l-1}} \int_{t_{l-1}+s_i}^{t_l+s_i} u(s) ds.$$

and  $u_j^n$  similarly. Let

$$(2.17) \quad \begin{cases} U_i(t) := \int_0^t u_i(s) dW(s) \\ U_j(t) := \int_0^t u_j(s) dW(s) \end{cases} \quad \begin{cases} U_i^n(t) := \int_0^t u_i^n(s) dW(s) \\ V_j^n(t) := \int_0^t u_j^n(s) dW(s). \end{cases}$$

Using (2.14) it is easy to check that

$$(2.18) \quad \lim_{n \rightarrow \infty} E \left| \sum_{l=1}^n \Delta_{li} U_i^n \Delta_{lj} U_j^n - \sum_{l=1}^n \Delta_{li} U_i \Delta_{lj} U_j \right| = 0.$$

By the formula for the Skorohod integral of a process multiplied by a random variable ([24], Theorem 3.2), we get

$$\begin{aligned} \Delta_{li} U_i^n &= \int_{t_{l-1}+s_i}^{t_l+s_i} \sum_{k=1}^n \frac{I_{(t_{k-1}+s_i, t_k+s_i]}(t)}{t_k - t_{k-1}} \int_{t_{k-1}+s_i}^{t_k+s_i} u_i(s) ds dW(t) \\ &= \frac{1}{t_l - t_{l-1}} \int_{t_{l-1}+s_i}^{t_l+s_i} u_i(s) ds [W(t_l + s_i) - W(t_{l-1} + s_i)] \\ &\quad + \frac{1}{t_l - t_{l-1}} \int_{t_{l-1}+s_i}^{t_l+s_i} \int_{t_{l-1}+s_i}^{t_l+s_i} D_t u_i(s) ds dt \\ &= P_{li} \Delta_{li} W + Q_{li}. \end{aligned}$$

where

$$P_{li} := \frac{1}{t_l - t_{l-1}} \int_{t_{l-1}+s_i}^{t_l+s_i} u_i(s) ds, \quad Q_{li} := \frac{1}{t_l - t_{l-1}} \int_{t_{l-1}+s_i}^{t_l+s_i} \int_{t_{l-1}+s_i}^{t_l+s_i} D_t u_i(s) ds dt.$$

Therefore,

$$\begin{aligned} \sum_{l=1}^n \Delta_{li} U_i^n \Delta_{lj} U_j^n &= \sum_{l=1}^n (P_{li} \Delta_{li} W + Q_{li})(P_{lj} \Delta_{lj} W + Q_{lj}) \\ &= \sum_{l=1}^n (P_{li} P_{lj})(\Delta_{li} W \Delta_{lj} W) + \sum_{l=1}^n (P_{li} Q_{lj}) \Delta_{li} W \\ &\quad + \sum_{l=1}^n (P_{lj} Q_{li}) \Delta_{lj} W + \sum_{l=1}^n Q_{li} Q_{lj}. \end{aligned}$$

By Hölder's inequality,

$$(2.19) \quad \sum_{l=1}^n Q_{li}^2 \leq \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \int_{t_{l-1}+s_i}^{t_l+s_i} |D_t u_i(s)|^2 ds dt.$$

Thus  $\lim_{n \rightarrow \infty} E \sum_{l=1}^n Q_{li}^2 = 0$ . Now

$$\begin{aligned} \sum_{l=1}^n (P_{li} \Delta_{li} W)^2 &= \sum_{l=1}^n \frac{(\Delta_{li} W)^2}{(t_l - t_{l-1})^2} \left( \int_{t_{l-1}+s_i}^{t_l+s_i} u_i(s) ds \right)^2 \\ &= \sum_{l=1}^n \frac{(\Delta_{li} W)^2}{t_l - t_{l-1}} \int_{t_{l-1}+s_i}^{t_l+s_i} (u_i^n(s))^2 ds. \end{aligned}$$

It is easy to check that  $E \|(u_i^n)^2\|_{L^2([0, a+s_i])} \leq E \|u_i^2\|_{L^2([0, a+s_i])}$  and

$$(2.20) \quad \lim_{n \rightarrow \infty} E \|(u_i^n)^2 - u_i^2\|_{L^2([0, a+s_i])} = 0.$$

By an argument similar to the one used in the proof of Lemma A.1, we can show that

$\{\sum_{l=1}^n (P_{li} \Delta_{li} W)^2, n \geq 1\}$  is uniformly integrable. Applying Lemma A.1, we have

$$(2.21) \quad \lim_{n \rightarrow \infty} E \left| \sum_{l=1}^n (P_{li} \Delta_{li} W)^2 - \int_0^{a+s_i} u_i^2(s) ds \right| = 0.$$

The Cauchy-Schwartz type inequality

$$(2.22) \quad E \left| \sum_{l=1}^n (P_{li} \Delta_{li} W) Q_{li} \right| \leq \sqrt{E \sum_{l=1}^n (P_{li} \Delta_{li} W)^2 E \sum_{l=1}^n Q_{li}^2}$$

together with (2.19) and (2.21) implies that  $\lim_{n \rightarrow \infty} E \left| \sum_{l=1}^n (P_{li} \Delta_{li} W) Q_{li} \right| = 0$ .

Now consider the case  $i \neq j$ . The Cauchy-Schwartz inequality implies

$$(2.23) \quad E \left| \sum_{l=1}^n Q_{lj} Q_{li} \right| \leq \sqrt{E \sum_{l=1}^n Q_{lj}^2 E \sum_{l=1}^n Q_{li}^2}.$$

We may write

$$\begin{aligned} \sum_{l=1}^n (P_{li} P_{lj}) (\Delta_{li} W \Delta_{lj} W) &= \sum_{l=1}^n \frac{\Delta_{li} W \Delta_{lj} W}{(t_l - t_{l-1})^2} \int_{t_{l-1}+s_i}^{t_l+s_i} u_i(s) ds \int_{t_{l-1}+s_j}^{t_l+s_j} u_j(s) ds \\ (2.24) \quad &= \sum_{l=1}^n \frac{\Delta_{li} W \Delta_{lj} W}{t_l - t_{l-1}} \int_{t_{l-1}+s_i}^{t_l+s_i} u_i^n(s) \hat{u}_j^n(s) ds, \end{aligned}$$

where

$$(2.25) \quad \hat{u}_j^n(s) = \sum_{l=1}^m \frac{I_{(t_{l-1}+s_i, t_l+s_i]}(s)}{t_l - t_{l-1}} \int_{t_{l-1}+s_i}^{t_l+s_i} u_j(s' + s_j - s_i) ds'.$$

Similar to the case  $i = j$ , we have

$$(2.26) \quad \lim_{n \rightarrow \infty} E \left| \sum_{l=1}^n (P_{li} P_{lj}) (\Delta_{li} W \Delta_{lj} W) \right| = 0.$$

This completes the proof of the proposition.  $\square$

Suppose that

$$\bar{X}_{t_l} = X_{t_{l-1}} + \alpha_l (X_{t_l} - X_{t_{l-1}}),$$

for some random variables  $0 \leq \alpha_l \leq 1$ ,  $l = 1, \dots, n$ . Denote

$$(2.27) \quad \Delta(\Pi(X_{t_l})) = (\Pi(\Delta X_{t_l})) = \Pi(X_{t_l}) - \Pi(X_{t_{l-1}}),$$

$$(2.28) \quad \Pi(\bar{X}_{t_l}) = \Pi(X_{t_{l-1}}) + \alpha_l \Delta \Pi(X_{t_l}),$$

$$(2.29) \quad \Delta_{li} X = X(t_l + s_i) - X(t_{l-1} + s_i), \text{ for } 1 \leq i \leq k \text{ and } 1 \leq l \leq n.$$

**Proposition 2.5.**

Suppose that  $\phi \in C^{1,2}(T \times \mathbf{R}^k, \mathbf{R})$ , and let  $1 \leq i, j \leq k$ . Under the hypotheses of Proposition 2.4, we have

$$(2.30) \quad \sum_{l=1}^n \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(\bar{X}_{t_l})) \Delta_{li} X \Delta_{lj} X \rightarrow \begin{cases} \int_0^{t+s_i} \frac{\partial^2 \phi}{\partial x_i^2}(s, \Pi(X_s)) u^2(s) ds, & i = j \\ 0, & i \neq j \end{cases}$$

as  $n \rightarrow \infty$ , in probability.

*Proof.*

For  $1 \leq i, j \leq k$ ,

$$(2.31) \quad \begin{aligned} \Delta_{li} X \Delta_{lj} X &= (\Delta_{li} U + \Delta_{li} V)(\Delta_{lj} U + \Delta_{lj} V) \\ &= \Delta_{li} U \Delta_{lj} U + \Delta_{li} U \Delta_{lj} V + \Delta_{li} V \Delta_{lj} U + \Delta_{li} V \Delta_{lj} V, \end{aligned}$$

where  $U, V$  are defined by (2.2). Since  $U, V$  are continuous and  $V[[0, a]$  is of bounded variation, it follows that

$$(2.32) \quad \begin{cases} \lim_{n \rightarrow \infty} \sum_{l=1}^n \Delta_{li} U \Delta_{lj} V = 0 \\ \lim_{n \rightarrow \infty} \sum_{l=1}^n \Delta_{li} V \Delta_{lj} U = 0 \\ \lim_{n \rightarrow \infty} \sum_{l=1}^n \Delta_{li} V \Delta_{lj} V = 0 \end{cases}$$

in probability, for all  $0 \leq i, j \leq n$ . To handle the term  $\sum_{l=1}^n \Delta_{li} U \Delta_{lj} U$ , we adapt an approach by Nualart and Pardoux (c.f. [24], Theorem 3.4, or [25], Theorem 3.2.1).

Set  $Y(s) := \frac{\partial^2 \phi}{\partial x_i^2}(s, \Pi(X_s)) I_{[0, t]}(s)$  and

$$(2.33) \quad Y^n(s) := Y(0) I_{\{0\}}(s) + \sum_{l=1}^n \frac{\partial^2 \phi}{\partial x_i^2}(t_{l-1}, \Pi(\bar{X}_{t_l})) I_{(t_{l-1}, t_l]}(s).$$

Then  $Y^n(s) \rightarrow Y(s)$  as  $n \rightarrow \infty$ , uniformly in  $s \in [0, t]$ . Applying Proposition 2.4 and Lemma A.2, we get

$$(2.34) \quad \sum_{l=1}^n \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(\bar{X}_{t_l})) \Delta_{li} X \Delta_{lj} X \rightarrow \delta_{ij} \int_0^{t+s_i} \frac{\partial^2 \phi}{\partial x_i^2}(s, \Pi(X_s)) u^2(s) ds$$

in probability as  $n \rightarrow \infty$ .  $\square$

### Proposition 2.6.

Suppose that  $\phi \in C^{1,2}(T \times \mathbf{R}^k)$  and let  $X(t)$  be a continuous stochastic process defined by (2.1), where  $u \in \mathbb{L}_{loc}^{2,4}$ ,  $v \in \mathbb{L}_{loc}^{1,4}$ , and  $\eta \in C([-\tau, 0], \mathbf{R}^m)$  is of bounded variation. Assume that  $\pi_n : -\tau = s_0 < \dots < s_n = 0$  are partitions of  $[-\tau, 0]$  such that  $|\pi_n| \rightarrow 0$  as  $n \rightarrow \infty$ . Then, for each  $1 \leq i \leq k$  and each  $t \in T$ , we have

$$(2.35) \quad \begin{aligned} & \lim_{n \rightarrow \infty} \sum_{l=1}^n \frac{\partial \phi}{\partial x_i}(t_{l-1}, \Pi(X_{t_{l-1}})) \Delta_{li} X \\ &= \int_0^t \frac{\partial \phi}{\partial x_i}(s, \Pi(X_s)) dX(s + s_i) + \sum_{j=i+1}^k \int_0^t \frac{\partial^2 \phi}{\partial x_i \partial x_j}(s, \Pi(X_s)) u^2(s + s_i) ds \\ &+ \sum_{j=1}^k \int_0^t \frac{\partial^2 \phi}{\partial x_i \partial x_j}(s, \Pi(X_s)) \left[ \int_0^{s+s_j} D_{s+s_i} u(r) dW(r) + \int_0^{s+s_j} D_{s+s_i} v(r) dr \right] u(s + s_i) ds \end{aligned}$$

in probability.

*Proof.*

By a localization argument, we may assume that  $\phi \in C_b^{1,2}(T \times \mathbf{R}^k, \mathbf{R})$ . Let  $|\pi_n| < \min_{\{1 \leq i \leq k\}} |s_i - s_{i-1}|$ . Fix  $1 \leq i \leq k, 1 \leq l \leq n$ , and set

$$(2.36) \quad F_l := \frac{\partial \phi}{\partial x_i}(t_{l-1}, \Pi(X_{t_{l-1}})).$$

By property of the Skorohod integral ([24], Theorem 3.2), it follows that

$$(2.37) \quad F_l \Delta_{li} U = \int_{t_{l-1}+s_i}^{t_l+s_i} u(s) F_l dW(s) + \int_{t_{l-1}+s_i}^{t_l+s_i} D_r(F_l) u(r) dr,$$

where  $U$  is defined by (2.2). The chain rule (for weak derivatives) yields

$$(2.38) \quad D_r(F_l) = \sum_{j=1}^k \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) D_r X(t_{l-1} + s_j).$$

Now, taking the Malliavin derivative  $D_r$  in (2.1) gives

$$(2.39) \quad D_r X(t) = u(r) I_{\{r \leq t\}} + \int_0^t D_r u(s) dW(s) + \int_0^t D_r v(s) ds.$$

Consequently

$$\sum_{l=1}^n \frac{\partial \phi}{\partial x_i}(t_{l-1}, \Pi(X_{t_{l-1}})) \Delta_{li} U = c_1 + c_2 + c_3 + c_4,$$

where

$$(2.40) \quad \begin{cases} c_1 := \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \frac{\partial \phi}{\partial x_i}(t_{l-1}, \Pi(X_{t_{l-1}})) u(s) dW(s) \\ c_2 := \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \sum_{j=1}^k \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) I_{\{r \leq t_{l-1}+s_j\}} u^2(r) dr \\ c_3 := \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \sum_{j=1}^k \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) \int_0^{t_{l-1}+s_j} D_r u(s) dW(s) u(r) dr \\ c_4 := \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \sum_{j=1}^k \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) \int_0^{t_{l-1}+s_j} D_r v(s) ds u(r) dr. \end{cases}$$

We will study the limits of the above expressions as  $n \rightarrow \infty$ .

Step 1. First we show that the limit of  $c_2$  is given by

$$(2.41) \quad c_2 \rightarrow \sum_{j=i+1}^k \int_0^{t+s_i} \frac{\partial^2 \phi}{\partial x_i \partial x_j}(r - s_i, \Pi(X_{r-s_i})) u^2(r) dr, \quad \text{a.s.}$$

If  $j \leq i$ , then  $t_{l-1} + s_i \geq t_{l-1} + s_j$ . So when  $t_{l-1} + s_i < r < t_l + s_i$ ,  $I_{\{r \leq t_{l-1} + s_j\}} = 0$ .

We have

$$\begin{aligned} c_2 &= \sum_{j=i+1}^k \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) I_{\{r \leq t_{l-1} + s_j\}} u^2(r) dr \\ &\rightarrow \sum_{j=i+1}^k \int_0^{t+s_i} \frac{\partial^2 \phi}{\partial x_i \partial x_j}(r - s_i, \Pi(X_{r-s_i})) u^2(r) dr \end{aligned}$$

a.s. as  $n \rightarrow \infty$ .

Step 2. Next we study the limit of  $c_3$  as  $n \rightarrow \infty$ . We claim that

$$(2.42) \quad c_3 \rightarrow \sum_{j=1}^k \int_0^{t+s_i} \frac{\partial^2 \phi}{\partial x_i \partial x_j}(r - s_i, \Pi(X_{r-s_i})) \int_0^{r-s_i+s_j} D_r u(s) dW(s) u(r) dr$$

as  $k \rightarrow \infty$  in probability. In fact,

$$\begin{aligned} T_j^n &:= \left| \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \left[ \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) \int_0^{t_{l-1}+s_j} D_r u(s) dW(s) \right. \right. \\ &\quad \left. \left. - \int_0^{t+s_i} \frac{\partial^2 \phi}{\partial x_i \partial x_j}(r - s_i, \Pi(X_{r-s_i})) \int_0^{r-s_i+s_j} D_r u(s) dW(s) \right] u(r) dr \right| \\ &\leq \left| \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) \int_{t_{l-1}+s_j}^{r+s_j-s_i} D_r u(s) dW(s) u(r) dr \right| \\ &\quad + \left| \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \left[ \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) - \frac{\partial^2 \phi}{\partial x_i \partial x_j}(r - s_i, \Pi(X_{r-s_i})) \right] \right. \\ &\quad \left. \times \int_0^{r-s_i+s_j} D_r u(s) dW(s) u(r) dr \right| \\ &\leq \left\| \frac{\partial^2 \phi}{\partial x_i \partial x_j} \right\|_{\infty} \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \left| \int_{t_{l-1}+s_j}^{r+s_j-s_i} D_r u(s) dW(s) \right| |u(r)| dr \\ &\quad + \sup_{1 \leq l \leq n} \sup_{r \in [t_{l-1}+s_i, t_l+s_i]} \left| \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) - \frac{\partial^2 \phi}{\partial x_i \partial x_j}(r - s_i, \Pi(X_{r-s_i})) \right| \\ &\quad \times \int_0^{t_l+s_i} \left| \int_0^{r-s_i+s_j} D_r u(s) dW(s) u(r) \right| dr \\ &= T_{j1}^n + T_{j2}^n, \end{aligned}$$

where  $T_{j1}^n$  and  $T_{j2}^n$  denote the first and second term on the right hand side of the last inequality. Using the Cauchy-Schwartz inequality and the  $L^p$  inequality for Skorohod integral ([24] Proposition 3.5, [25] p.158), we have

$$\begin{aligned} ET_{j1}^n &\leq \left\| \frac{\partial^2 \phi}{\partial x_i \partial x_j} \right\|_{\infty} \left( E \int_0^{a+s_i} u^2(r) dr \right)^{\frac{1}{2}} \\ &\quad \times \left\{ E \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \int_{t_{l-1}+s_j}^{r+s_j-s_i} |D_r u(s)|^2 ds dr \right. \\ &\quad \left. + E \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \int_{t_{l-1}+s_j}^{r+s_j-s_i} \int_0^a |D_{\theta}(D_r u(s))|^2 d\theta ds dr \right\}^{\frac{1}{2}} \\ &\rightarrow 0 \end{aligned}$$

as  $n \rightarrow \infty$ . The uniform continuity of  $\frac{\partial^2 \phi}{\partial x_i \partial x_j}$  implies  $T_{j2}^n \rightarrow 0$  a.s. So as  $n \rightarrow \infty$ ,  $T_j^n \rightarrow 0$  in probability.

Step 3. Now we will show that

$$(2.43) \quad c_4 \rightarrow \sum_{j=1}^k \int_0^{t+s_i} \frac{\partial^2 \phi}{\partial x_i \partial x_j}(r-s_i, \Pi(X_{r-s_i})) \int_0^{r+s_j-s_i} D_r v(s) ds u(r) dr, \quad \text{a.s.}$$

As in Step 2, we have

$$\begin{aligned} &\left| \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \left[ \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) \int_0^{t_{l-1}+s_j} D_r v(s) ds \right. \right. \\ &\quad \left. \left. - \frac{\partial^2 \phi}{\partial x_i \partial x_j}(r-s_i, \Pi(X_{r-s_i})) \int_0^{r-s_i+s_j} D_r v(s) ds \right] u(r) dr \right| \\ &\leq \left\| \frac{\partial^2 \phi}{\partial x_i \partial x_j} \right\|_{\infty} \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \left| \int_{t_{l-1}+s_j}^{r+s_j-s_i} D_r v(s) ds \right| |u(r)| dr \\ &+ \sup_{1 \leq l \leq n} \sup_{r \in [t_{l-1}+s_i, t_l+s_i]} \left| \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) - \frac{\partial^2 \phi}{\partial x_i \partial x_j}(r-s_i, \Pi(X_{r-s_i})) \right| \\ &\quad \times \int_0^{t_l+s_i} \left| \int_0^{r-s_i+s_j} D_r v(s) ds \right| |u(r)| dr \\ &\rightarrow 0 \quad \text{a.s as } n \rightarrow \infty. \end{aligned}$$

Step 4. Finally, we study the limit of  $c_1$  as  $n \rightarrow \infty$ . We shall show that

$$(2.44) \quad c_1 \rightarrow \int_0^{t+s_i} \frac{\partial \phi}{\partial x_i}(s-s_i, \Pi(X_{s-s_i})) u(s) dW(s)$$

in  $L^2(\Omega, \mathbf{R})$  as  $n \rightarrow \infty$ . To see this, define

$$(2.45) \quad u^n(s) = u(s) \sum_{l=1}^n \frac{\partial \phi}{\partial x_i}(t_{l-1}, \Pi(X_{t_{l-1}})) I_{(t_{l-1}+s_i, t_l+s_i]}(s).$$

It suffices to show that

$$(2.46) \quad u^n(s) \rightarrow \frac{\partial \phi}{\partial x_i}(s - s_i, \Pi(X_{t_{s-s_i}})) u(s) I_{(0, t+s_i]}(s)$$

in  $\mathbb{L}^{1,2}$  as  $n \rightarrow \infty$ . It is clear that the sequence  $\{u^n(s)\}$  converges to

$$\frac{\partial \phi}{\partial x_i}(s - s_i, \Pi(X_{s-s_i})) u(s) I_{(0, t+s_i]}(s) \text{ in } L^2(\Omega \times T, \mathbf{R}). \text{ It remains to show that the sequence } \{D_r u^n(s)\}_{n=1}^\infty, r, s \in T^2, \text{ converges in } L^2(\Omega \times T^2, \mathbf{R}) \text{ to } D_r \left[ \frac{\partial \phi}{\partial x_i}(s - s_i, \Pi(X_{s-s_i})) u(s) I_{(0, t+s_i]}(s) \right].$$

Now

$$\begin{aligned} & D_r u^n(s) \\ &= D_r u(s) \sum_{l=1}^n \frac{\partial \phi}{\partial x_i}(t_{l-1}, \Pi(X_{t_{l-1}})) I_{(t_{l-1}+s_i, t_l+s_i]}(s) \\ &+ u(s) \sum_{l=1}^n \left[ \sum_{j=1}^k \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) \int_0^{t_{l-1}+s_j} D_r u(s') dW(s') \right] I_{(t_{l-1}+s_i, t_l+s_i]}(s) \\ &+ u(s) \sum_{l=1}^n \left[ \sum_{j=1}^k \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) \int_0^{t_{l-1}+s_j} D_r v(s') ds' \right] I_{(t_{l-1}+s_i, t_l+s_i]}(s) \\ &+ u(s) \sum_{l=1}^n \left[ \sum_{j=1}^k \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) u(r) I_{[0, t_{l-1}+s_j]}(r) \right] I_{(t_{l-1}+s_i, t_l+s_i]}(s) \\ &= d_1 + d_2 + d_3 + d_4. \end{aligned}$$

where  $d_1, d_2, d_3, d_4$  stand for the first, second, third and fourth term on the right hand side of the above equality, respectively. It is easy to see that

$$d_1 \rightarrow D_r u(s) \frac{\partial \phi}{\partial x_i}(\Pi(s - s_i, X_{s-s_i})) I_{(0, t+s_i]}(s)$$

in  $L^2(\Omega, \mathbf{R})$ . Since for all  $1 \leq j \leq k$ ,  $u(s) \int_0^{s+s_j-s_i} D_r v(\theta) d\theta$  belongs to  $L^2(\Omega \times T^2, \mathbf{R})$ , then by Lebesgue's dominated convergence theorem, the  $L^2(\Omega \times T^2, \mathbf{R})$  limit of the function  $q_3(s, r)$  defined by

$$q_3 := u(s) \sum_{j=1}^k \sum_{l=1}^n \left[ \frac{\partial^2 \phi}{\partial x_i \partial x_j}(t_{l-1}, \Pi(X_{t_{l-1}})) \int_0^{s+s_j-s_i} D_r v(\theta) d\theta \right] I_{(t_{l-1}+s_i, t_l+s_i]}(s)$$

is

$$\sum_{j=1}^k u(s) \left[ \frac{\partial^2 \phi}{\partial x_i \partial x_j} (s - s_i, \Pi(X_{s-s_i})) \int_0^{s+s_j-s_i} D_r v(\theta) d\theta \right] I_{(0, t+s_i]}(s)$$

Since  $v \in \mathbb{L}^{1,4}$  and  $u \in L^4(\Omega \times T, \mathbf{R})$ , the following argument shows the difference between  $d_3$  and  $q_3$  converges to 0 as  $n \rightarrow \infty$  in  $L^1(\Omega, \mathbf{R})$ :

$$\begin{aligned} & \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \int_0^a u^2(s) \left[ \frac{\partial^2 \phi}{\partial x_i \partial x_j} (t_{l-1}, \Pi(X_{t_{l-1}})) \right]^2 \left[ \int_{t_{l-1}+s_j}^{s+s_j-s_i} D_r v(\theta) d\theta \right]^2 dr ds \\ & \leq |\pi_n| \left\| \frac{\partial^2 \phi}{\partial x_i \partial x_j} \right\|_\infty^2 \int_0^a u^2(s) ds \int_0^a \int_0^a (D_r v(\theta))^2 dr d\theta \\ & \rightarrow 0 \end{aligned}$$

Hence, the  $L^2(\Omega \times T^2, \mathbf{R})$  limit of  $d_3$  is the same as that of  $q_3$ , namely,

$$\sum_{j=1}^k u(s) \left[ \frac{\partial^2 \phi}{\partial x_i \partial x_j} (s - s_i, \Pi(X_{s-s_i})) \int_0^{s+s_j-s_i} D_r v(\theta) d\theta \right] I_{(0, t+s_i]}(s)$$

in  $L^2(\Omega \times T^2, \mathbf{R})$ . To find the limit of  $d_2$ , we need to check that for all  $j$ , the two parameter process  $(u(s) \int_0^{s+s_j-s_i} D_r u(\theta) dW(\theta), 0 \leq s, r \leq a)$  belongs to  $L^2(\Omega \times T^2, \mathbf{R})$ . This follows from the following estimates:

$$\begin{aligned} & E \int_0^a \int_0^a u^2(s) \left[ \int_0^{s+s_j-s_i} D_r u(\theta) dW(\theta) \right]^2 ds dr \\ & \leq \left\{ E \int_0^a u^4(s) ds E \int_0^a \left( \int_0^a \left[ \int_0^{s+s_j-s_i} D_r u(\theta) dW(\theta) \right]^2 dr \right)^2 ds \right\}^{\frac{1}{2}} \\ & \leq C \left\{ E \int_0^a u^4(s) ds \left[ E \left( \int_0^a \int_0^a |D_r u(\theta)|^2 d\theta dr \right)^2 \right. \right. \\ & \quad \left. \left. + E \left( \int_0^a \int_0^a \int_0^a D_\alpha(D_r u(\theta)) d\theta dr d\alpha \right)^2 \right] \right\}^{\frac{1}{2}}. \end{aligned}$$

Here we have used a slight modification of the  $L^p$  estimate of the Skorohod integral for  $p = 4$  (c.f. [25], Exercise 3.2.7). Using similar  $L^p$  estimates to the above, we obtain

$$\begin{aligned} (2.47) \quad & \sum_{l=1}^n \int_{t_{l-1}+s_i}^{t_l+s_i} \int_0^a u^2(s) \left[ \frac{\partial^2 \phi}{\partial x_i \partial x_j} (t_{l-1}, \Pi(X_{t_{l-1}})) \right]^2 \left[ \int_{t_{l-1}+s_j}^{s+s_j-s_i} D_r u(\theta) dW(\theta) \right]^2 dr ds \\ & \leq \left\| \frac{\partial^2 \phi}{\partial x_i \partial x_j} \right\|_\infty^2 \left( \int_0^a E u^4(s) ds \right)^{\frac{1}{2}} \times \left\{ \sum_{l=1}^n E \int_{t_{l-1}+s_i}^{t_l+s_i} \left[ \int_0^a \left( \int_{t_{l-1}+s_j}^{s+s_j-s_i} D_r v(\theta) d\theta \right)^2 dr \right]^2 ds \right\}^{\frac{1}{2}}. \end{aligned}$$

Note that the right hand side of the above inequality tends to zero as  $n \rightarrow \infty$ . Thus

$$(2.48) \quad d_2 \rightarrow \sum_{j=1}^k u(s) \left[ \frac{\partial^2 \phi}{\partial x_i \partial x_j}(s - s_i, \Pi(X_{s-s_i})) \int_0^{s+s_j-s_i} D_r u(\theta) dW(\theta) \right] I_{(0, t+s_i]}(s)$$

in  $L^2(\Omega \times T^2, \mathbf{R})$  as  $n \rightarrow \infty$ .

It is easy to check that

$$d_4 \rightarrow \sum_{j=1}^k u(s) \frac{\partial^2 \phi}{\partial x_i \partial x_j}(s - s_i, \Pi(X_{s-s_i})) u(r) I_{[0, s+s_j-s_i]}(r) I_{(0, t+s_i]}(s)$$

as  $n \rightarrow \infty$  in  $L^2(\Omega, \mathbf{R})$ . Therefore,

$$(2.49) \quad D_r u^n(s) \rightarrow D_r [u(s) \frac{\partial^2 \phi}{\partial x_i \partial x_j}(s - s_i, \Pi(X_{s-s_i})) I_{(0, t+s_i]}(s)]$$

in  $L^2(\Omega \times T^2, \mathbf{R})$ . Finally it is easy to see that

$$c_1 \rightarrow \int_0^{t+s_i} \frac{\partial \phi}{\partial x_i}(s - s_i, \Pi(X_{s-s_i})) u(s) dW(s)$$

in  $L^2(\Omega, \mathbf{R})$  as  $n \rightarrow \infty$ .

Step 5. The convergence

$$(2.50) \quad \sum_{l=1}^n \frac{\partial \phi}{\partial x_i}(t_{l-1}, \Pi(X_{t_{l-1}})) \Delta_{l_i} V \rightarrow \int_{s_i}^{t+s_i} \frac{\partial \phi}{\partial x_i}(s - s_i, \Pi(X_{s-s_i})) dV(s) \text{ a.s.}$$

as  $n \rightarrow \infty$ , is easy to verify.  $\square$

We complete the section by giving a Stratonovich version of the Itô formula (2.7).

Suppose that  $k \geq 1$  and  $p \geq 2$ . The set  $\mathbb{L}_{d,C}^{k,p}$  (c.f. [24] Definition 7.2, [25] p.167) is the class of processes  $u \in L_d^{k,p}$  such that the mappings  $s \mapsto D_{s \wedge t} u(s \vee t)$  and  $s \mapsto D_{s \vee t} u(s \wedge t)$  are continuous in  $L^p(\Omega)$ , uniformly in  $t$ , and  $\sup_{s,t \in T} E(|D_s u(t)|^p) < \infty$ .

The space  $\mathbb{L}_{d,C,loc}^{1,2}$  is the class of processes that are locally in  $\mathbb{L}_{d,C}^{1,2}$ . For any  $u \in \mathbb{L}_{d,C}^{1,2}$ , the following limits

$$(2.51) \quad \begin{cases} D_t^+ u(t) = \lim_{\epsilon \downarrow 0} \sum_{i=1}^d D_t^i u^i(t + \epsilon) \\ D_t^- u(t) = \lim_{\epsilon \downarrow 0} \sum_{i=1}^d D_t^i u^i(t - \epsilon) \end{cases}$$

exist in  $L^2(\Omega)$  uniformly in  $t$ , we set  $\nabla = D^+ + D^-$ , i.e.,  $(\nabla u)(t) = D_t^+ u(t) + D_t^- u(t)$ .

Consider the process

$$(2.52) \quad X(t) = \begin{cases} \eta(0) + \int_0^t u(s) \circ dW(s) + \int_0^t v(s) ds, & t > 0 \\ \eta(t), & -\tau \leq t \leq 0, \end{cases}$$

where  $\eta$  belongs to  $C$  and is of bounded variation,  $u = (u^1, \dots, u^m)^T$ ,  $u^i \in \mathbb{L}_{d,C,loc}^{2,4}$ ,  $(\nabla u) \in \mathbb{L}_{loc}^{1,4}$ ,  $v = (v^1, \dots, v^m)^T$ ,  $v^i \in \mathbb{L}_{loc}^{1,4}$ , and the stochastic integral is a Stratonovich one. Assume also that the process  $X$  is continuous.

Using the relationship between the Skorohod and Stratonovich integrals ([24], Theorem 7.3; [25], Theorem 3.11) and Theorem 2.3, we can easily obtain the following Stratonovich version of Itô's formula for the segment process  $X_t$  (cf. [32]).

**Corollary 2.8.**

*Suppose that the process  $X(t)$  is defined by (2.52), and let  $\phi \in C^{1,2}(T \times \mathbf{R}^{mk}, \mathbf{R})$ .*

*Then*

$$(2.53) \quad \begin{aligned} & \phi(t, \Pi(X_t)) - \phi(0, \Pi(X_0)) \\ &= \int_0^t \frac{\partial \phi}{\partial s}(s, \Pi(X_s)) ds + \sum_{i=1}^k \int_0^t \frac{\partial \phi}{\partial \bar{x}^i}(s, \Pi(X_s)) u(s + s_i) \circ dW(s + s_i) \\ & \quad + \sum_{i=1}^k \int_0^t \frac{\partial \phi}{\partial \bar{x}^i}(s, \Pi(X_s)) v(s + s_i) ds. \end{aligned}$$

*for all  $t \in T$  a.s..*

**3. Weak differentiability of solutions of SDDE's.**

In this section, we will study the weak differentiability of the solution of the Itô SDDE (1.6). Bell and Mohammed ([5]) have applied the Malliavin calculus to study regularity of solutions of SDDE's with a single delay in the noise term. Their analysis relies on weak differentiability of the solution of the SDDE. In Section 8 of this article, the weak differentiability of the solution to the SDDE (1.6) together with the Itô formula (2.10) are used to develop higher order numerical schemes for solving the SDDE. The next

three results (Proposition 3.1, Lemma 3.2, and Proposition 3.3) are analogous to those in Nualart ([25] Theorem 2.2.1, Lemma 2.2.2, and Theorem 2.2.2). Denote  $\mathbb{D}_m^{k,\infty} := \cap_{p \geq 2} \mathbb{D}_m^{k,p}$ , for  $k \in N$ . Recall that  $D_r^l, 1 \leq l \leq d$ , stand for weak differentiation with respect to the  $l$ -th component of  $W$ .

**Proposition 3.1.** (c.f. [25], Proposition 1.2.3).

In the Itô SDDE (1.6), assume that  $g \in C_b^{0,1}(T \times \mathbf{R}^{k_1 m}, L(\mathbf{R}^d, \mathbf{R}^m))$  and  $h \in C_b^{0,1}(T \times \mathbf{R}^{k_2 m}, \mathbf{R}^m)$ . Let  $X$  be the solution of (1.6). Then  $X(t) \in \mathbb{D}_m^{1,\infty}$  for all  $t \in T$ , and

$$(3.1) \quad \sup_{0 \leq r \leq a} E\left(\sup_{r \leq s \leq a} |D_r X(s)|^p\right) < \infty$$

for all  $p \geq 2$ . Furthermore, the ‘‘partial’’ weak derivatives  $D_r^l X^j(t)$  with respect to the  $l$ -th coordinate of  $W$  satisfy the following linear SDDE’s a.s.:

$$(3.2) \quad D_r^l X^j(t) = \begin{cases} g^{jl}(r, \Pi_1(X_r^j)) + \int_r^t \sum_{i=1}^{k_1} \frac{\partial g^{jl}}{\partial \vec{x}_i}(s, \Pi_1(X_s)) D_r^l X^j(s + s_{1,i}) dW^l(s) \\ + \int_0^t \sum_{i=1}^{k_2} \frac{\partial h^j}{\partial \vec{x}_i}(s, \Pi_2(X_s)) D_r^l X^j(s + s_{2,i}) ds, & t \geq r, \\ = 0, & t < r, \end{cases}$$

for  $l = 1, \dots, d, j = 1, \dots, m$ . In (3.2),  $g^{jl}$  is the  $(j, l)$  entry of the  $m \times d$  matrix  $g$ , and  $h^j$  is the  $j$ -th coordinate of  $h$ .

*Proof.*

For simplicity, we will only consider the one-dimensional case  $d = m = 1$ .

$$X^0(t) = \begin{cases} \eta(0), & t \geq 0 \\ \eta(t), & -\tau \leq t < 0, \end{cases}$$

$$(3.3) \quad X^{n+1}(t) = \eta(0) + \int_0^t g(s, \Pi_1(X_s^n)) dW(s) + \int_0^t h(s, \Pi_2(X_s^n)) ds.$$

It is easy to see that

$$(3.4) \quad \begin{aligned} D_r \left( \int_0^t g(s, \Pi_1(X_s^n)) dW(s) \right) \\ = g(r, \Pi_1(X_r^n)) + \int_{r-s_1, k_1}^t D_r(g(s, \Pi_1(X_s^n))) dW(s) \end{aligned}$$

and

$$(3.5) \quad D_r \left( \int_0^t h(s, \Pi_2(X_s^n)) ds \right) = \int_{r-s_2, k_2}^t D_r(h(s, \Pi_2(X_s^n))) ds.$$

Since  $g$  and  $h$  have bounded space derivatives, it is easy to see that there is a positive constant  $K$  such that

$$(3.6) \quad \begin{cases} D_r(g(s, \Pi_1(X_s^n))) \leq K \sup_{r \leq u \leq s} |D_r X^n(u)| \\ D_r(h(s, \Pi_2(X_s^n))) \leq K \sup_{r \leq u \leq s} |D_r X^n(u)|, \end{cases}$$

almost surely. From the Burkholder-Davis-Gundy inequality and (3.3)-(3.6), it follows that  $X^n(t) \in \mathbb{D}^{1,\infty}$  for all  $t \in [0, a]$ , and there are positive constants  $C_1, C_2$  such that

$$(3.7) \quad E \left( \sup_{r \leq u \leq t} |D_r X^{n+1}(u)|^p \right) \leq C_1 (1 + E \|X_r^n\|_C^p) + C_2 \int_r^t E \left( \sup_{r \leq u \leq s} |D_r X^n(u)|^p \right) ds.$$

By induction on  $n$ , the above inequality implies that  $E \left( \sup_{r \leq s \leq a} |D_r X^n(s)|^p \right)$  are uniformly bounded in  $n$  for all  $p \geq 2$ . By [25], proposition 1.5.5, it follows that  $X(t) \in \mathbb{D}^{1,\infty}$  for all  $t$ . Applying the operator  $D$  to (1.6) (and using [25] Proposition 1.2.3), we obtain the linear SDDE (3.2) for the weak derivative of  $X(t)$ . The estimate (3.1) follows from (3.2), Burkholder-Davis-Gundy's inequality and Gronwall's lemma.  $\square$

The following lemma may be proved using similar ideas. Its proof is left to the reader.

**Lemma 3.2.**

*Suppose that the real-valued process  $\alpha = \{\alpha(r, t) : t \in [r, a]\}$  is adapted and continuous. Assume that the processes  $a(t) = (a_1(t), \dots, a_{k_1}(t)) \in \mathbf{R}^{k_1}$  and  $b(t) = (b_1(t), \dots, b_{k_2}(t)) \in \mathbf{R}^{k_2}$  are adapted, continuous and uniformly bounded. Furthermore, suppose that the random variables  $\alpha(r, t)$ ,  $a(t)$  and  $b(t)$  belong to  $\mathbb{D}^{1,\infty}$  and satisfy the conditions*

$$(3.8) \quad \begin{cases} \sup_{0 \leq r \leq a} E \left( \sup_{r \leq t \leq a} |\alpha(r, t)|^p \right) + \sup_{0 \leq r, s \leq a} E \left( \sup_{s \leq t \leq a} |D_s \alpha(r, t)|^p \right) < \infty \\ \sup_{0 \leq s \leq a} \left\{ E \left( \sup_{s \leq t \leq a} |a(t)|^p \right) + E \left( \sup_{s \leq t \leq a} |D_s a(t)|^p \right) \right\} < \infty \\ \sup_{0 \leq s \leq a} \left\{ E \left( \sup_{s \leq t \leq a} |b(t)|^p \right) + E \left( \sup_{s \leq t \leq a} |D_s b(t)|^p \right) \right\} < \infty \end{cases}$$

for all  $p \geq 2$ . Let  $Y = \{Y(t) : t \in [0, a]\}$  be the solution of the linear SDDE

$$(3.9) \quad Y(t) = \begin{cases} \alpha(r, t) + \int_r^t \langle a(s), \Pi_1(Y_s) \rangle_{\mathbf{R}^{k_1}} dW(s) + \int_r^t \langle b(s), \Pi_2(Y_s) \rangle_{\mathbf{R}^{k_2}} ds, & t \geq r, \\ 0, & 0 \leq t \leq r. \end{cases}$$

Then  $Y(t)$  belongs to  $\mathbb{D}^{1, \infty}$ , and for all integers  $p \geq 2$ , we have

$$(3.10) \quad \begin{cases} \sup_{0 \leq s \leq a} E( \sup_{s \leq t \leq a} |D_s Y(t)|^p ) < \infty \\ \sup_{0 \leq s \leq a} E( \sup_{s \leq t \leq a} |Y(t)|^p ) < \infty. \end{cases}$$

Furthermore, the weak derivative  $D_s Y(t)$  of  $Y(t)$  satisfies the linear SDDE

$$(3.11) \quad \begin{aligned} D_s Y(t) &= D_s \alpha(r, t) + \langle a(s), \Pi_1(Y_s) \rangle_{\mathbf{R}^{k_1}} I_{\{r \leq s \leq t\}} \\ &\quad + \int_r^t [ \langle D_s a(v), \Pi_1(Y_v) \rangle_{\mathbf{R}^{k_1}} + \langle a(v), \Pi_1(D_s Y_v) \rangle_{\mathbf{R}^{k_1}} ] dW(v) \\ &\quad + \int_r^t [ \langle D_s b(v), \Pi_2(Y_v) \rangle_{\mathbf{R}^{k_2}} + \langle b(v), \Pi_2(D_s Y_v) \rangle_{\mathbf{R}^{k_2}} ] dv, \quad s < t. \end{aligned}$$

The next proposition follows from Proposition 3.1 and Lemma 3.2.

**Proposition 3.3.**

Let  $X = \{X(t) : t \in T = [0, a]\}$  be the solution of the SDDE (1.6), where  $g \in C_b^{0,2}(T \times \mathbf{R}^{k_1 m}, L(\mathbf{R}^d, \mathbf{R}^m))$ ,  $h \in C_b^{0,2}(T \times \mathbf{R}^{k_2 m}, \mathbf{R}^m)$  have bounded first and second partial derivatives in the space variables. Then  $X(t) \in \mathbb{D}_m^{2, \infty}$  for all  $t \in T$ , and

$$(3.12) \quad \sup_{0 \leq r_1, r_2 \leq a} E( \sup_{r_1 \vee r_2 \leq s \leq a} |D_{r_1}^{l_1} D_{r_2}^{l_2} X(s)|^p ) < \infty$$

for  $l_1, l_2 = 1, \dots, d$ , and all  $p \geq 2$ .

**4. Strong approximation of multiple Stratonovich integrals.**

The following iterated Stratonovich integrals are used in the Milstein scheme for the SDDE (1.6):

$$(4.1) \quad J_{i,j}(t_0, t_1; -b) := \int_{t_0+b}^{t_1+b} \int_{t_0}^{s-b} \circ dW^i(v) \circ dW^j(s),$$

where  $0 < t_0 < t_1, b \geq 0$ .

We will adopt the discretization scheme in [17] (section 5.8) in order to handle the above double stochastic integral. For alternative discretization approaches to iterated stochastic integrals, see [12] and [29].

Set

$$(4.2) \quad J(t_0, t_1; -b) := J_{1,1}(t_0, t_1; -b),$$

$t := t_1 - t_0$  and  $r := 2\pi/t$ . We choose a complete orthonormal basis of  $L^2[0, t]$  as

$$(4.3) \quad \left\{ \frac{1}{\sqrt{t}}, \sqrt{\frac{2}{t}} \sin nrs, \sqrt{\frac{2}{t}} \cos nrs : n = 1, 2, \dots, 0 \leq s \leq t \right\}.$$

Set  $\bar{W}^i(s) := W^i(s + t_0) - W^i(t_0)$  and  $\bar{B}^j(s) := \bar{W}^j(s + b) - \bar{W}^j(b)$ ,  $s \geq 0, 1 \leq i, j \leq d$ .

Using the Kahunen-Loève expansion technique, we have

$$(4.4) \quad \bar{W}^i(s) - \frac{s}{t} \bar{W}^i(t) = \frac{a_0^i(t)}{2} + \sum_{n=1}^{\infty} [a_n^i(t) \cos nrs + b_n^i(t) \sin nrs]$$

and

$$(4.5) \quad \bar{B}^j(s) - \frac{s}{t} \bar{B}^j(t) = \frac{a_0^{j,b}(t)}{2} + \sum_{n=1}^{\infty} [a_n^{j,b}(t) \cos nrs + b_n^{j,b}(t) \sin nrs]$$

where

$$(4.6) \quad \begin{cases} a_n^i(t) = \frac{2}{t} \int_0^t (\bar{W}^i(s) - \frac{s}{t} \bar{W}^i(t)) \cos nrs \, ds \\ b_n^i(t) = \frac{2}{t} \int_0^t (\bar{W}^i(s) - \frac{s}{t} \bar{W}^i(t)) \sin nrs \, ds \end{cases}$$

and

$$(4.7) \quad \begin{cases} a_n^{j,b}(t) = \frac{2}{t} \int_0^t (\bar{B}^j(s) - \frac{s}{t} \bar{B}^j(t)) \cos nrs \, ds \\ b_n^{j,b}(t) = \frac{2}{t} \int_0^t (\bar{B}^j(s) - \frac{s}{t} \bar{B}^j(t)) \sin nrs \, ds \end{cases}$$

for  $n \geq 1$ . The convergences in (4.4) and (4.5) are in  $L^2(\Omega \times [0, t])$ . It is easy to see that if  $n \geq 1$ ,  $a_n^i(t)$ ,  $b_n^i(t)$ ,  $a_n^{j,b}(t)$  and  $b_n^{j,b}(t)$  are normally distributed with mean 0 and variance  $t/2\pi^2 n^2$  ([18], p.198). Furthermore,  $\{a_n^i(t), b_n^i(t)\}$  and  $\{a_n^{j,b}(t), b_n^{j,b}(t)\}$  are pairwise independent ([18], p. 198). One can use well-known random number generators to simulate these random coefficients (c.f. [11], section 3.1.2, [18], section 1.3, and [19], section 1.2).

**Lemma 4.1.**

Let  $t_0, t \geq 0$ . Then

$$(4.8) \quad \begin{aligned} J_{i,j}(t_0, t_0 + t; -b) &= \frac{1}{2}(\bar{W}^i(t)\bar{B}^j(t)) - \frac{1}{2}(\bar{W}^i(t)a_0^{j,b}(t_0) - \bar{B}^j(t)a_0^i(t_0)) \\ &\quad + \pi \sum_{n=1}^{\infty} n[a_n^i(t_0)b_n^{j,b}(t_0) - b_n^i(t_0)a_n^{j,b}(t_0)], \quad 1 \leq i, j \leq d, \end{aligned}$$

where the infinite series converges in  $L^2(\Omega, \mathbf{R})$ .

*Proof.*

It suffices to show (4.8) for  $t_0 = 0$ . Fix  $t > 0$ . For simplicity of notation, we write

$$(4.9) \quad a_n^j = a_n^j(0), \quad b_n^j = b_n^j(0), \quad a_n^{j,b} = a_n^{j,b}(0), \quad b_n^{j,b} = b_n^{j,b}(0)$$

and

$$(4.10) \quad W_N^i(s) = \frac{s}{t}W^i(t) + \frac{a_0^i}{2} + \sum_{n=1}^N (a_n^i \cos nrs + b_n^i \sin nrs),$$

It is easy to check that

$$(4.11) \quad \int_b^{t+b} \int_0^{s-b} \circ dW_N^i(v) \circ dW^j(s) \rightarrow \int_b^{t+b} \int_0^{s-b} \circ dW^i(v) \circ dW^j(s)$$

in  $L^2(\Omega)$  as  $N \rightarrow \infty$ . Then we may write

$$\begin{aligned} J_{i,j}(0, t; -b) &= \int_b^{t+b} W^i(s-b) \circ dW^j(s) \\ &= \int_b^{t+b} \frac{s-b}{t} W^i(t) \circ dW^j(s) + \frac{a_0^i}{2} \bar{B}^j(t) \\ &\quad + \sum_{n=1}^{\infty} [a_n^i \int_b^{t+b} \cos nr(s-b) dW^j(s) + b_n^i \int_b^{t+b} \sin nr(s-b) dW^j(s)]. \end{aligned}$$

For any  $n \geq 1$ , we have

$$\begin{aligned}
\int_b^{t+b} \cos nr(s-b) dW^j(s) &= \int_0^t \cos nrs d\bar{B}^j(s) \\
&= \int_0^t \cos nrs d(\bar{B}^j(s) - \frac{s}{t}\bar{B}^j(t)) + \int_0^t \cos nrs d(\frac{s}{t}\bar{B}^j(t)) \\
&= \cos nrs(\bar{B}^j(s) - \frac{s}{t}\bar{B}^j(t)) \Big|_0^t + nr \int_0^t (\bar{B}^j(s) - \frac{s}{t}\bar{B}^j(t)) \sin nrs ds \\
&\quad + \frac{\bar{B}^j(t)}{t} \int_0^t \cos nrs ds \\
&= \frac{t}{2} nr b_n^{j,b}.
\end{aligned}$$

Similarly, we have

$$(4.12) \quad \int_b^{t+b} \sin nr(s-b) dW^j(s) = -\frac{t}{2} nr a_n^{j,b}.$$

So

$$(4.13) \quad J_{i,j}(0,t;-b) = \frac{W^i(t)}{t} \int_0^t s d\bar{B}^j(s) + \frac{a_0^i}{2} \bar{B}^j(t) + \pi \sum_{n=1}^{\infty} n(a_n^i b_n^{j,b} - b_n^i a_n^{j,b}).$$

Now,

$$\begin{aligned}
\int_0^t s d\bar{B}^j(s) &= t\bar{B}^j(t) - \int_0^t \bar{B}^j(s) ds \\
&= \frac{t}{2} \bar{B}^j(t) - \int_0^t (\bar{B}^j(s) - \frac{s}{t}\bar{B}^j(t)) ds \\
&= \frac{t}{2} (\bar{B}^j(t) - a_0^{j,b}).
\end{aligned}$$

Therefore,

$$(4.14) \quad J_{i,j}(0,t;-b) = \frac{1}{2} W^i(t) \bar{B}^j(t) - \frac{1}{2} (W^i(t) a_0^{j,b} - \bar{B}^j(t) a_0^i) + \pi \sum_{n=1}^{\infty} n(a_n^i b_n^{j,b} - b_n^i a_n^{j,b}).$$

□

The expansion of  $J_{i,j}(0,t;-b)$  is a generalization of the expansion of

$$\begin{aligned}
(4.15) \quad \int_0^t \int_0^s \circ dW^i(v) \circ dW^j(s) &= \frac{1}{2} (W^i(t) W^j(t)) - \frac{1}{2} [W^i(t) a_0^{j,b} - W^j(t) a_0^i] \\
&\quad + \pi \sum_{n=1}^{\infty} n(a_n^i b_n^j - b_n^i a_n^j)
\end{aligned}$$

(see [12], [18], and [19]). Set

(4.16)

$$\begin{aligned} J_{i,j}^p(t_0, t_0 + t; -b) &:= \frac{1}{2}(\bar{W}^i(t)\bar{B}^j(t)) - \frac{1}{2}[\bar{W}^i(t)a_0^{j,b}(t_0) - \bar{B}^j(t)a_0^i(t_0)] \\ &\quad + \pi \sum_{n=1}^p n[a_n^i(t_0)b_n^{j,b}(t_0) - b_n^i(t_0)a_n^{j,b}(t_0)]. \end{aligned}$$

Then  $J_{i,j}^p(t_0, t_0 + t; -b)$  can be used to approximate  $J_{i,j}(t_0, t_0 + t; -b)$  in the mean square.

The rate of convergence is given in Lemma 4.2 below.

**Lemma 4.2.**

*For any integer  $p \geq 1$  and  $t > 0$ , we have*

$$(4.17) \quad E|J_{i,j}^p(0, t; -b) - J_{i,j}(0, t; -b)|^2 \leq \frac{t^2}{2\pi^2 p}.$$

*Proof.*

Let  $p \geq 1$  be any integer. Then

$$(4.18) \quad \sum_{n=p+1}^{\infty} \frac{1}{n^2} \leq \int_p^{\infty} \frac{1}{u^2} du = \frac{1}{p}.$$

Since  $a_n^i$  and  $b_n^i$  are independent,  $E(a_n^i b_n^i) = 0$  and  $E(a_n^{j,b} b_n^{j,b}) = 0$ , we have

$$\begin{aligned} E|J_{i,j}^p(0, t; -b) - J_{i,j}(0, t; -b)|^2 &= \pi^2 \sum_{n=p+1}^{\infty} n^2 E(a_n^i b_n^{j,b} - b_n^i a_n^{j,b})^2 \\ &= \pi^2 \sum_{n=p+1}^{\infty} n^2 [E(a_n^i b_n^{j,b})^2 + E(b_n^i a_n^{j,b})^2] \\ &= \frac{t^2}{2\pi^2} \sum_{n=p+1}^{\infty} \frac{1}{n^2} \leq \frac{t^2}{2\pi^2 p}. \quad \square \end{aligned}$$

## 5. The strong Milstein scheme.

In this section we construct a strong Milstein scheme of order 1 for the SDDE (1.6). Our construction relies heavily on the Itô formula for “tame” functions (Theorem 2.3).

Throughout this section, we assume that in (1.6) the coefficients  $g \in C^{1,2}(T \times \mathbf{R}^{k_1 m}, L(\mathbf{R}^d, \mathbf{R}^m))$  and  $h \in C^{1,2}(T \times \mathbf{R}^{k_2 m}, \mathbf{R}^m)$ . For convenience, set  $W(s) = W(0) = 0$ , for all  $s \leq 0$ . We also define

$$(5.1) \quad u(t) := \begin{cases} g(t, \Pi_1(X_t)), & 0 \leq t \leq a, \\ 0, & t < 0, \end{cases} \quad \text{and} \quad v(t) := \begin{cases} h(t, \Pi_2(X_t)), & 0 \leq t \leq a, \\ \eta(t), & t < 0. \end{cases}$$

We first derive the Milstein scheme for the case  $d = m = 1$ .

### 5.1. Itô-Taylor expansion.

Assume that  $0 < t_0 < t$ , and  $\vec{x} = (x_1, \dots, x_{k_1}) \in \mathbf{R}^{k_1}$ . Applying the Itô formula (2.10), we have

$$(5.2) \quad \begin{aligned} & g(t, \Pi_1(X_t)) - g(t_0, \Pi_1(X_{t_0})) \\ &= \int_{t_0}^t \frac{\partial g}{\partial s}(s, \Pi_1(X_s)) ds + \sum_{i=1}^{k_1} \int_{t_0+s_{1,i}}^{t+s_{1,i}} \frac{\partial g}{\partial x_i}(s - s_{1,i}, \Pi_1(X_{s-s_{1,i}})) u(s) dW(s) \\ &+ \sum_{i=1}^{k_1} \int_{t_0}^t \left[ \frac{\partial g}{\partial x_i}(s, \Pi_1(X_s)) v(s + s_{1,i}) + \frac{1}{2} \left\langle \frac{\partial^2 g}{\partial x_i^2}(s, \Pi_1(X_s)) \nabla_{s_{1,i}}^+ X(s), \nabla_{s_{1,i}}^- X(s) \right\rangle \right] ds, \end{aligned}$$

where  $\nabla_{s_{1,i}}^\pm X(s)$  are defined by (2.9). Applying the Itô formula (2.10) again and using similar notations for  $h$ , we obtain

$$(5.3) \quad \begin{aligned} & h(t, \Pi_2(X_t)) - h(t_0, \Pi_2(X_{t_0})) \\ &= \int_{t_0}^t \frac{\partial h}{\partial s}(s, \Pi_2(X_s)) ds + \sum_{i=1}^{k_2} \int_{t_0+s_{2,i}}^{t+s_{2,i}} \frac{\partial h}{\partial x_i}(s - s_{2,i}, \Pi_2(X_{s-s_{2,i}})) u(s) dW(s) \\ &+ \frac{1}{2} \sum_{i=1}^{k_2} \int_{t_0}^t \left[ \frac{\partial h}{\partial x_i}(s, \Pi_2(X_s)) v(s + s_{2,i}) + \frac{1}{2} \left\langle \frac{\partial^2 h}{\partial x_i^2}(s, \Pi_2(X_s)) \nabla_{s_{2,i}}^+ X(s), \nabla_{s_{2,i}}^- X(s) \right\rangle \right] ds. \end{aligned}$$

Substituting (5.2) and (5.3) into (1.6), we get the following approximate (Itô-Taylor) expansion of (1.6):

$$(5.4) \quad \begin{aligned} X(t) &= X(t_0) + g(t_0, \Pi_1(X_{t_0})) [W(t) - W(t_0)] + h(t_0, \Pi_2(X_{t_0}))(t - t_0) \\ &+ \sum_{i=1}^{k_1} \frac{\partial g}{\partial x_i}(t_0, \Pi_1(X_{t_0})) u(t_0 + s_{1,i}) \int_{t_0}^t \int_{t_0+s_{1,i}}^{t_1+s_{1,i}} dW(t_2) dW(t_1) + R(t_0, t), \end{aligned}$$

where

$$(5.5) \quad \begin{aligned} R(t_0, t) &:= \sum_{i=1}^{k_1} \left\{ \int_{t_0}^t \int_{t_0+s_{1,i}}^{t_1+s_{1,i}} \left[ \frac{\partial g}{\partial x_i}(t_2 - s_{1,i}, \Pi_1(X_{t_2-s_{1,i}})) u(t_2) - \frac{\partial g}{\partial x_i}(t_0, \Pi_1(X_{t_0})) \right. \right. \\ &\quad \left. \left. \times u(t_0 + s_{1,i}) \right] dW(t_2) dW(t_1) \right\} + \int_{t_0}^t \int_{t_0}^{t_1} \sum_{i=1}^{k_1} \left[ \frac{\partial g}{\partial x_i}(t_2, \Pi_1(X_{t_2})) v(t_2 + s_{1,i}) \right. \\ &\quad \left. + \frac{1}{2} \left\langle \frac{\partial^2 g}{\partial x_i^2}(t_2, \Pi_1(X_{t_2})) \nabla_{s_{1,i}}^+ X_{t_2}, \nabla_{s_{1,i}}^- X_{t_2} \right\rangle \right] dt_2 dW(t_1) \\ &+ \sum_{i=1}^{k_2} \int_{t_0}^t \int_{t_0+s_{2,i}}^{t_1+s_{2,i}} \frac{\partial h}{\partial x_i}(t_2 - s_{2,i}, \Pi_2(X_{t_2-s_{2,i}})) u(t_2) dW(t_2) dt_1 \\ &+ \int_{t_0}^t \int_{t_0}^{t_1} \sum_{i=1}^{k_2} \left[ \frac{\partial h}{\partial x_i}(t_2, \Pi_2(X_{t_2})) v(t_2 + s_{2,i}) \right. \\ &\quad \left. + \frac{1}{2} \left\langle \frac{\partial^2 h}{\partial x_i^2}(t_2, \Pi_2(X_{t_2})) \nabla_{s_{2,i}}^+ X_{t_2}, \nabla_{s_{2,i}}^- X_{t_2} \right\rangle \right] dt_2 dt_1 \\ &+ \int_{t_0}^t \int_{t_0}^{t_1} \left[ \frac{\partial g}{\partial t_2}(t_2, \Pi_1(X_{t_2})) + \frac{\partial h}{\partial t_2}(t_2, \Pi_2(X_{t_2})) \right] dt_2 dt_1. \end{aligned}$$

In the above expression, the stochastic integrals

$$\int_{t_0+s_{1,i}}^{t_1+s_{1,i}} \frac{\partial g}{\partial x_i}(t_2 - s_{1,i}, \Pi_1(X_{t_2-s_{1,i}})) u(t_2) dW(t_2)$$

and

$$\int_{t_0+s_{2,i}}^{t_1+s_{2,i}} \frac{\partial h}{\partial x_i}(t_2 - s_{2,i}, \Pi_2(X_{t_2-s_{2,i}})) u(t_2) dW(t_2)$$

are Skorohod integrals. Define

$$(5.6) \quad I(t_0 + s_{i,j}, t + s_{i,j}; s_{i,j}) := \int_{t_0}^t \int_{t_0+s_{i,j}}^{t_1+s_{i,j}} dW(t_2) dW(t_1),$$

for  $i = 1, 2$  and  $j = 1, \dots, k_i$ . Recall the definition of  $J(t_0 + s_{i,j}, t + s_{i,j}; s_{i,j})$  in (4.1). Note that if  $s_{i,j} < 0$ , then

$$(5.7) \quad I(t_0 + s_{i,j}, t + s_{i,j}; s_{i,j}) = \int_{t_0}^t \int_{t_0 + s_{i,j}}^{t_1 + s_{i,j}} \circ dW(t_2) \circ dW(t_1);$$

if  $s_{i,j} = 0$ , then

$$(5.8) \quad I(t_0 + s_{i,j}, t + s_{i,j}; s_{i,j}) = \int_{t_0}^t [W(t_1) - W(t_0)] dW(t_1) = \frac{(W(t) - W(t_0))^2}{2} - \frac{t - t_0}{2}.$$

## 5.2. The one-dimensional Milstein scheme ( $d = m = 1$ ).

Assume  $d = m = 1$ . Let  $\pi : -\tau = t_{-l} < \dots < t_0 = 0 < \dots < t_n = a$  be a partition of  $[-\tau, a]$ . We introduce the *Milstein* scheme for the SDDE (1.6) as follows:

$$(5.9) \quad \begin{aligned} X^\pi(t) = & X^\pi(t_k) + h(t_k, \Pi_2(X_{t_k}^\pi))(t - t_k) + g(t_k, \Pi_1(X_{t_k}^\pi))(W(t) - W(t_k)) \\ & + \sum_{i=1}^{k_1} \frac{\partial g}{\partial x_i}(t_k, \Pi_1(X_{t_k}^\pi)) u^\pi(t_k + s_{1,i}) I(t_k + s_{1,i}, t + s_{1,i}; s_{1,i}), \end{aligned}$$

for  $t_k < t \leq t_{k+1}$ , where

$$u^\pi(t) = \begin{cases} g(t, \Pi_1(X_t^\pi)), & t \geq 0, \\ 0, & -\tau \leq t < 0, \end{cases}$$

and

$$I(t_k + s_{1,i}, t + s_{1,i}; s_{1,i}) = \int_{t_k}^t \int_{t_k + s_{1,i}}^{t_1 + s_{1,i}} \circ dW(t_2) \circ dW(t_1).$$

Recall the notation

$$[s] := \begin{cases} t_k, & \text{if } t_k \leq s < t_{k+1} \\ t_{n_t}, & \text{if } t_{n_t} \leq s \leq t. \end{cases}$$

and introduce the following notation:

$$\lceil s \rceil = \begin{cases} t_{k+1}, & t_k < s \leq t_{k+1}, \\ t, & t_{n_t} < s \leq t. \end{cases}$$

In view of (5.7) and Lemma 4.2, we will use  $J^p(t_i, t; s_{1,i})$  to approximate  $I(t_i, t; s_{1,i})$ .

Denote by

$$Z^\pi(t) := X^\pi(t) - X(t), \quad t \in [-\tau, a]$$

the global truncation error for the Milstein scheme, with  $X$  the unique solution of the SDDE (1.6).

**Lemma 5.1.**

In the SDDE (1.6) (with  $d = m = 1$ ), suppose that  $g \in C_b^2(\mathbf{R}^{k_1}, \mathbf{R})$ ,  $h \in C_b^2(\mathbf{R}^{k_2}, \mathbf{R})$ , have bounded first and second derivatives. Then for each integer  $p \geq 1$ , there exists a constant  $K(p) > 0$  such that

$$(5.10) \quad \begin{cases} E(\langle \frac{\partial^2 g}{\partial \bar{x}^2}(s, \Pi_1(X_s)) \nabla_{s_1, i}^+ X_s, \nabla_{s_1, i}^- X_s \rangle^p) \leq K(p) \\ E(\langle \frac{\partial^2 h}{\partial \bar{x}^2}(s, \Pi_2(X_s)) \nabla_{s_2, i}^+ X_s, \nabla_{s_2, i}^- X_s \rangle^p) \leq K(p) \end{cases}$$

for all  $t \in [0, a]$ .

*Proof.*

By the definition of  $\nabla_{s_2, i}^\pm X(s)$  (see (2.9)), we have

$$(5.11) \quad \begin{aligned} \nabla_{s_1, i, s_1, j}^+ X(s) &= 2u(s + s_{1, i})I_{\{s_{1, i} < s_{1, j}\}} + u(s + s_{1, i})\delta_{ij} \\ &+ 2 \int_0^{s+s_{1, j}} D_{s+s_{1, i}} u(r) dW(r) + 2 \int_0^{s+s_{1, j}} D_{s+s_{1, i}} v(r) , dr, \end{aligned}$$

and

$$(5.12) \quad \nabla_{s_1, i, s_1, j}^- X(s) = u(s + s_{1, i})\delta_{ij}.$$

Therefore,

$$(5.13) \quad \begin{aligned} &\langle \frac{\partial^2 g}{\partial \bar{x}^2}(s, \Pi_1(X_s)) \nabla_{s_1, i}^+ X(s), \nabla_{s_1, i}^- X(s) \rangle \\ &= 2 \sum_{i=1}^{k_1} \left\{ \frac{\partial^2 g}{\partial x_i \partial x_j}(s, \Pi_1(X_s)) u(s + s_{1, i}) [u(s + s_{1, i}) I_{\{s_{1, i} < s_{1, j}\}} + \frac{1}{2} u(s + s_{1, i}) \delta_{ij} \right. \\ &\quad \left. + \int_0^{s+s_{1, j}} D_{s+s_{1, i}} u(r) dW(r) + \int_0^{s+s_{1, j}} D_{s+s_{1, i}} v(r) dr \right\}. \end{aligned}$$

If  $r > 0$ , then

$$(5.14) \quad D_s u(r) = D_s g(\Pi_1(X_r)) = \sum_{i=1}^{k_1} \frac{\partial g}{\partial x_i}(r, \Pi_1(X_r)) D_s X(r + s_{1, i}),$$

and

$$(5.15) \quad \begin{aligned} D_t D_s u(r) &= \sum_{i,j=1}^{k_1} \frac{\partial^2 g}{\partial x_i \partial x_j}(r, \Pi_1(X_r)) D_s X(r + s_{1,i}) D_t X(r + s_{1,j}) \\ &\quad + \sum_{i=1}^{k_1} \frac{\partial g}{\partial x_i}(r, \Pi_1(X_r)) D_t D_s X(r + s_{1,i}). \end{aligned}$$

By Proposition 3.1 and Proposition 3.3, there exists a constant  $C_1 > 0$  such that

$$\begin{cases} \sup_{0 \leq s \leq a} E( \sup_{s \leq r \leq a} |D_s X(r)|^2 ) \leq C_1 \\ \sup_{0 \leq s, t \leq a} E( \sup_{s \vee t \leq r \leq a} |D_t D_s X(r)|^2 ) \leq C_1. \end{cases}$$

Since  $g$  has bounded first and second derivatives, then there is a positive constant  $C_2$  such that

$$\sup_{0 \leq s \leq a} E( \sup_{s \leq r \leq a} |D_s u(r)|^2 ) \leq C_2 k_1 \sup_{0 \leq s \leq a} E( \sup_{s \leq r \leq a} |D_s X(r)|^2 ) \leq C_1 C_2 k_1,$$

and

$$\sup_{0 \leq s, t \leq a} E( \sup_{s \vee t \leq r \leq a} |D_t D_s u(r)|^2 ) \leq C_1^2 C_2^2 k_1 + C_1 C_2 k_1.$$

If  $r < s + s_{1,i}$ , then

$$\begin{cases} D_{s+s_{1,i}} u(r) = 0 \\ D_{s+s_{1,i}} v(r) = 0. \end{cases}$$

Therefore,

$$\begin{aligned} &E( \int_{t+s_{1,i}}^{t+s_{1,j}} D_{t+s_{1,i}} u(r) dW(r) )^2 \\ &\leq \int_{t+s_{1,i}}^{t+s_{1,j}} \int_{t+s_{1,i}}^{t+s_{1,j}} E( D_s D_{t+s_{1,i}} u(r) )^2 dr ds + \int_{t+s_{1,i}}^{t+s_{1,j}} E( D_{t+s_{1,i}} u(r) )^2 dr \\ &\leq C_2 k_1^2 C_1^2 + 2C_2 k_1 C_1 =: K_1. \end{aligned}$$

Similarly, there exists a constant  $K_2 > 0$  such that

$$E( \int_{t+s_{1,i}}^{t+s_{1,j}} D_{t+s_{1,i}} v(r) dr )^2 \leq K_2.$$

So the first inequality of (5.10) follows from the above two inequalities and the Lipschitz and bounded conditions on  $h, g$  ((1.4),(1.5)). The second estimate of (5.10) is proved by a similar argument.  $\square$

**Theorem 5.2.**

Consider the Milstein scheme (5.9) for the SDDE (1.6). Recall that  $Z^\pi := X^\pi - X$  is the global truncation error for any partition  $\pi$  of  $[-\tau, a]$ . Let  $0 < \gamma \leq 1$ . Suppose that  $\eta : [-\tau, 0] \rightarrow \mathbf{R}^m$  is of bounded variation and is  $(\frac{\gamma}{2})$ -Hölder continuous. Let  $g \in C^{1,2}(T \times \mathbf{R}^{k_1}, \mathbf{R})$ ,  $h \in C^{1,2}(T \times \mathbf{R}^{k_2}, \mathbf{R})$  have bounded first and second spatial derivatives. Assume that

$$\sup_{-\tau \leq s \leq 0} |Z^\pi(s)| \leq C' |\pi|^\gamma$$

for some positive constant  $C'$ . Then there exists a constant  $C > 0$  (depending on  $a$  and independent of  $\pi$ ) such that

$$\sup_{-\tau \leq s \leq a} E|Z^\pi(s)|^2 \leq C |\pi|^{2\gamma}.$$

*Proof.*

As in the proof of Theorem 2.4, we express the global error in the form

$$Z^\pi(t) = Z^\pi(0) + I^\pi(t) - R^\pi(t),$$

where

$$\begin{aligned} I^\pi(t) &= \sum_{i=1}^{n_t} [h(t_{i-1}, \Pi_2(X^\pi(t_{i-1}))) - h(t_{i-1}, \Pi_2(X(t_{i-1})))](t_i - t_{i-1}) \\ &+ \sum_{i=1}^{n_t} [g(t_{i-1}, \Pi_1(X^\pi(t_{i-1}))) - g(t_{i-1}, \Pi_1(X(t_{i-1})))](W(t_i) - W(t_{i-1})) \\ &+ [h(t_{n_t}, \Pi_2(X^\pi(t_{n_t}))) - h(t_{n_t}, \Pi_2(X(t_{n_t})))](t - t_{n_t}) \\ &+ [g(t_{n_t}, \Pi_1(X^\pi(t_{n_t}))) - g(t_{n_t}, \Pi_1(X(t_{n_t})))](W(t) - W(t_{n_t})) \\ &+ \sum_{i=1}^{n_t} \sum_{j=1}^{k_1} \left\{ I(t_{i-1}, t_i; s_{1,j}) \left[ \frac{\partial g}{\partial x_j}(t_{i-1}, \Pi_1(X^\pi(t_{i-1}))) \right. \right. \\ &\times u^\pi(t_{i-1} + s_{1,j}) - \left. \frac{\partial g}{\partial x_j}(t_{i-1}, \Pi_1(X(t_{i-1}))) u(t_{i-1} + s_{1,j}) \right] \Big\} + \sum_{j=1}^{k_1} \left\{ I_{t_{n_t}, t_i; s_{1,j}} \right. \\ &\times \left. \left[ \frac{\partial g}{\partial x_j}(t_{n_t}, \Pi_1(X^\pi(t_{n_t}))) u^\pi(t_{n_t} + s_{1,j}) - \frac{\partial g}{\partial x_j}(t_{n_t}, \Pi_1(X(t_{n_t}))) u(t_{n_t} + s_{1,j}) \right] \right\}, \end{aligned}$$

and

$$R^\pi(t) = \sum_{i=1}^{n_t} R(t_{i-1}, t_i) + R(t_{n_t}, t).$$

We shall decompose  $R^\pi(t)$  into five parts:

$$R^\pi(t) = R_1^\pi(t) + R_2^\pi(t) + R_3^\pi(t) + R_4^\pi(t) + R_5^\pi(t),$$

where

$$\begin{aligned} R_1^\pi(t) &:= \sum_{i=1}^{n_t} \sum_{j=1}^{k_1} \left\{ \int_{t_{i-1}}^{t_i} \int_{t_{i-1}+s_{1,j}}^{s+s_{1,j}} \left[ \frac{\partial g}{\partial x_j}(r - s_{1,j}, \Pi_1(X_{r-s_{1,j}})) u(r) \right. \right. \\ &\quad \left. \left. - \frac{\partial g}{\partial x_j}(t_{i-1}, \Pi_1(X_{t_{i-1}})) u(t_{i-1} + s_{1,j}) \right] dW(r) dW(s) \right\} + \sum_{j=1}^{k_1} \left\{ \int_{t_{n_t}}^t \int_{t_{n_t}+s_{1,j}}^{s+s_{1,j}} \right. \\ &\quad \left. \left[ \frac{\partial g}{\partial x_j}(r - s_{1,j}, \Pi_1(X_{r-s_{1,j}})) u(r) - \frac{\partial g}{\partial x_j}(t_{n_t}, \Pi_1(X_{t_{n_t}})) u(t_{n_t} + s_{1,j}) \right] dW(r) dW(s) \right\} \\ &= \sum_{j=1}^{k_1} \left\{ \int_0^t \int_{\lfloor s \rfloor + s_{1,j}}^{s+s_{1,j}} \left[ \frac{\partial g}{\partial x_j}(r - s_{1,j}, \Pi_1(X_{r-s_{1,j}})) u(r) \right. \right. \\ &\quad \left. \left. - \frac{\partial g}{\partial x_j}(P_{\lfloor s \rfloor, \underline{s}_{1, k_1}}(X_{\lfloor s \rfloor})) u(\lfloor s \rfloor + s_{1,j}) \right] dW(r) dW(s) \right\}, \\ R_2^\pi(t) &:= \sum_{j=1}^{k_1} \int_0^t \int_{\lfloor s \rfloor}^s \left[ \frac{\partial g}{\partial x_j}(r, \Pi_1(X_r)) v(r + s_{1,j}) \right. \\ &\quad \left. + \frac{1}{2} \left\langle \frac{\partial^2 g}{\partial \vec{x}^2}(r, \Pi_1(X_r)) \nabla_{s_{1,j}}^+ X_r, \nabla_{s_{1,j}}^- X_r \right\rangle \right] dr dW(s), \\ R_3^\pi(t) &:= \sum_{j=1}^{k_2} \int_0^t \int_{\lfloor s \rfloor + s_{2,j}}^{s+s_{2,j}} \frac{\partial h}{\partial x_j}(r - s_{2,j}, \Pi_2(X_{r-s_{2,j}})) u(r) dW(r) ds, \\ R_4^\pi(t) &:= \sum_{j=1}^{k_2} \int_0^t \int_{\lfloor s \rfloor}^s \left[ \frac{\partial h}{\partial x_j}(r, \Pi_2(X_r)) v(r + s_{2,j}) \right. \\ &\quad \left. + \frac{1}{2} \left\langle \frac{\partial^2 h}{\partial \vec{x}^2}(r, \Pi_2(X_r)) \nabla_{s_{2,j}}^+ X_r, \nabla_{s_{2,j}}^- X_r \right\rangle \right] dr ds, \end{aligned}$$

and

$$R_5^\pi(t) := \int_0^t \int_{\lfloor s \rfloor}^s \left\{ \frac{\partial h}{\partial r}(r, \Pi_2(X_r)) + \frac{\partial g}{\partial r}(r, \Pi_1(X_r)) \right\} dr ds.$$

By the Itô isometry and the formula for covariance between two Skorohod integrals ([25], Section 1.3.1), we have

$$\begin{aligned}
\sup_{0 \leq s \leq t} E|R_1^\pi(s)|^2 &\leq k_1 \sum_{j=1}^{k_1} E \int_0^t \left\{ \int_{[s]+s_{1,j}}^{s+s_{1,j}} \left[ \frac{\partial g}{\partial x_j}(r - s_{1,j}, \Pi_1(X_{r-s_{1,j}}))u(r) \right. \right. \\
&\quad \left. \left. - \frac{\partial g}{\partial x_j}([s], \Pi_1(X_{[s]}))u([s] + s_{1,j}) \right] dW(r) \right\}^2 ds \\
&\leq k_1 \sum_{j=1}^{k_1} \int_0^t \int_{[s]+s_{1,j}}^{s+s_{1,j}} E \left[ \frac{\partial g}{\partial x_j}(r - s_{1,j}, \Pi_1(X_{r-s_{1,j}}))u(r) \right. \\
&\quad \left. - \frac{\partial g}{\partial x_j}([s], \Pi_1(X_{[s]}))u([s] + s_{1,j}) \right]^2 dr ds \\
&\quad + k_1 \sum_{j=1}^{k_1} \int_0^t \int_{[s]+s_{1,j}}^{s+s_{1,j}} \int_{[s]+s_{1,j}}^{s+s_{1,j}} E \left\{ D_{r_1} \left[ \frac{\partial g}{\partial x_j}(r - s_{1,j}, \Pi_1(X_{r-s_{1,j}}))u(r) \right. \right. \\
&\quad \left. \left. - \frac{\partial g}{\partial x_j}([s], \Pi_1(X_{[s]}))u([s] + s_{1,j}) \right] \right\}^2 dr_1 dr_2 ds \\
&= k_1 R_{11}^\pi(t) + k_1 R_{12}^\pi(t).
\end{aligned}$$

By assumption, the function  $G_j(s, x, z) = \frac{\partial g}{\partial x_j}(s, x)g(s + s_{1,j}, z)$ , ( $x \in \mathbf{R}^{k_1}$  and  $z \in \mathbf{R}^{k_1}$ ), is Lipschitz, i.e., there exists a constant  $L_1 > 0$  such that

$$|G_j(s, z) - G_j(s, w)| \leq L_1|z - w|, \quad \forall z, w \in \mathbf{R}^{2k_1} \text{ and } 1 \leq j \leq k_1.$$

Using

$$u(r) = \begin{cases} g(r, \Pi_1(X_r)), & r \geq 0 \\ 0, & r < 0, \end{cases}$$

and

$$\sup_{-\tau \leq r_1 \leq \alpha < \beta \leq r_2 \leq a} E|X(\beta) - X(\alpha)|^2 \leq C_2|r_2 - r_1|^\gamma,$$

it follows that

$$\begin{aligned}
R_{11}^\pi(t) &\leq \sum_{j=1}^{k_1} \int_0^t \int_{[s]+s_{1,j}}^{s+s_{1,j}} E[G_j(r - s_{1,j}, \Pi_1(X_{r-s_{1,j}}), \Pi_1(X_r)) \\
&\quad - G_j([s], \Pi_1(X_{[s]}), \Pi_1(X_{[s]+s_{1,j}}))]^2 I_{\{[s]+s_{1,j} \geq 0\}} dr ds \\
&\leq 2k_1 L_1^2 \sum_{j=1}^{k_1} \int_0^t \int_{[s]+s_{1,j}}^{s+s_{1,j}} \sup_{\substack{-1 \leq r_1 < r_2 \leq a \\ |r_2 - r_1| \leq |\pi|}} E|X(r_2) - X(r_1)|^2 dr ds \\
&\leq 2(a+1)k_1^2 L_1^2 C_2 |\pi|^{2\gamma}.
\end{aligned}$$

Now for all  $r \geq 0$  and  $1 \leq j \leq k_1$ ,

$$\begin{aligned} & D_s \left( \frac{\partial g}{\partial x_j} (r - s_{1,j}, \Pi_1(X_{r-s_{1,j}})) u(r) \right) \\ &= g(r, \Pi_1(X_r)) \sum_{i=1}^{k_1} \frac{\partial^2 g}{\partial x_j \partial x_i} (r - s_{1,j}, \Pi_1(X_{r-s_{1,j}})) D_s X(r - s_{1,j} + s_{1,i}) \\ &+ \frac{\partial g}{\partial x_j} (r - s_{1,j}, \Pi_1(X_{r-s_{1,j}})) \sum_{i=1}^{k_1} \frac{\partial g}{\partial x_i} (r, \Pi_1(X_r)) D_s X(r + s_{1,i}). \end{aligned}$$

By Proposition 3.1, there exists a constant  $C_3 > 0$  such that

$$\sup_{0 \leq r \leq a} E \left( \sup_{0 \leq s \leq a} |D_r X(s)|^2 \right) \leq C_3.$$

By (1.8), (1.10), and boundedness of the spatial derivatives of  $g$ , there exists a constant  $C_4 > 0$  such that

$$\sup_{0 \leq r \leq a} \sup_{0 \leq s \leq a} E \left( \left| D_s \left( \frac{\partial g}{\partial x_j} (r - s_{1,j}, \Pi_1(X_{r-s_{1,j}})) u(r) \right) \right|^2 \right) \leq 2C_4 k_1^2.$$

Therefore

$$\begin{aligned} R_{12}^\pi(t) &\leq k_1 \sum_{j=1}^{k_1} \int_0^t \int_{\lfloor s \rfloor + s_{1,j}}^{s+s_{1,j}} \int_{\lfloor s \rfloor + s_{1,j}}^{s+s_{1,j}} E \{ D_{r_1} [4C_4 k_1^2] dr_1 dr_2 ds \\ &\leq 4(a+1)C_4 k_1^4 |\pi|^2. \end{aligned}$$

Hence there is a constant  $C_5 > 0$  such that

$$(5.16) \quad \sup_{0 \leq s \leq t} E |R_1(s)|^2 \leq C_5 |\pi|^{2\gamma}.$$

Applying Fubini's theorem, we can rewrite  $R_3^\pi(t)$  as

$$\begin{aligned} R_3^\pi(t) &= \sum_{i=1}^{n_t} \sum_{j=1}^{k_2} \int_{t_{i-1}}^{t_i} \int_{t_{i-1} + s_{2,j}}^{s+s_{2,j}} \frac{\partial h}{\partial x_j} (r - s_{2,j}, \Pi_2(X_{r-s_{2,j}})) u(r) dW(r) ds \\ &+ \sum_{j=1}^{k_2} \int_{t_{n_t}}^t \int_{t_{n_t} + s_{2,1}}^{s+s_{2,j}} \frac{\partial h}{\partial x_j} (r - s_{2,j}, \Pi_2(X_{r-s_{2,j}})) u(r) dW(r) ds. \end{aligned}$$

So we have

$$\begin{aligned}
R_3^\pi(t) &= \sum_{i=1}^{n_t} \sum_{j=1}^{k_2} \int_{t_{i-1}+s_{2,j}}^{t_i+s_{2,j}} \int_{r-s_{2,j}}^{t_i} \frac{\partial h}{\partial x_j}(r-s_{2,j}, \Pi_2(X_{r-s_{2,j}})) u(r) ds dW(r) \\
&+ \sum_{j=1}^{k_2} \int_{t_{n_t}+s_{2,j}}^{t+s_{2,j}} \int_{r-s_{2,j}}^t \frac{\partial h}{\partial x_j}(r-s_{2,j}, \Pi_2(X_{r-s_{2,j}})) u(r) ds dW(r) \\
&= \sum_{i=1}^{n_t} \sum_{j=1}^{k_2} \int_{t_{i-1}+s_{2,j}}^{t_i+s_{2,j}} (t_i+s_{2,j}-r) \frac{\partial h}{\partial x_j}(r-s_{2,j}, \Pi_2(X_{r-s_{2,j}})) u(r) dW(r) \\
&+ \sum_{j=1}^{k_2} \int_{t_{n_t}+s_{2,j}}^{t+s_{2,j}} (t+s_{2,j}-r) \frac{\partial h}{\partial x_j}(r-s_{2,j}, \Pi_2(X_{r-s_{2,j}})) u(r) dW(r) \\
&= \sum_{j=1}^{k_2} \int_{s_{2,j}}^{t+s_{2,j}} (\lceil r-s_{2,j} \rceil + s_{2,j} - r) \frac{\partial h}{\partial x_j}(r-s_{2,j}, \Pi_2(X_{r-s_{2,j}})) u(r) dW(r).
\end{aligned}$$

Applying the formula for covariance between two Skorohod integrals ([25], Section 1.3.1) and Proposition 3.1, we can show that there exists a constant  $C_6 > 0$  such that

$$(5.17) \quad \sup_{0 \leq s \leq t} E|R_3(s)|^2 \leq C_6 |\pi|^2.$$

Similarly, by Lemma 5.1, we can easily show that there exist  $C_7 > 0$  such that

$$(5.18) \quad \begin{cases} \sup_{0 \leq s \leq t} E|R_2(s)|^2 \leq C_7 |\pi|^2, \\ \sup_{0 \leq s \leq t} E|R_4(s)|^2 \leq C_7 |\pi|^2 \\ \sup_{0 \leq s \leq t} E|R_5(s)|^2 \leq C_7 |\pi|^2 \end{cases}$$

By similar arguments to the ones used in the proof of Theorem 4.1, we obtain the following inequality

$$(5.19) \quad \sup_{0 \leq u \leq t} E|I^\pi(u)|^2 \leq C_1 \int_0^t \sup_{-\tau \leq u \leq s} E(|Z^\pi(u)|^2) ds$$

for some constant  $C_1 > 0$ . From (5.16)–(5.19), there exist  $C_8 > 0$  and  $C_9 > 0$  such that

$$(5.20) \quad \sup_{0 \leq u \leq t} E|Z^\pi(u)|^2 \leq E|Z^\pi(0)|^2 + C_8 |\pi|^{2\gamma} + C_9 \int_0^t \sup_{-\tau \leq u \leq s} E|Z^\pi(u)|^2 ds.$$

So

$$(5.21) \quad \sup_{-\tau \leq u \leq t} E|Z^\pi(u)|^2 \leq (2C' + C_8) |\pi|^{2\gamma} + C_9 \int_0^t \sup_{-\tau \leq u \leq s} E|Z^\pi(u)|^2 ds.$$

By Gronwall's lemma, there exists a constant  $C > 0$  such that

$$E \sup_{-\tau \leq s \leq t} |Z^\pi(s)|^2 \leq C|\pi|^{2\gamma}. \quad \square$$

*Remarks 5.3.*

(i) Let us consider a particular case when  $g$  and  $h$  are of the (linear) form

$$(5.22) \quad \begin{cases} g(s, \Pi_1(X_s)) = \sum_{i=1}^{k_1} a_i(s, X_s(s_{1,i})) \\ h(s, \Pi_2(X_s)) = \sum_{j=1}^{k_2} b_j(s, X_s(s_{2,j})), \end{cases}$$

where  $a_i, b_j \in C_b^{1,2}(T \times R)$  for  $1 \leq i \leq k_1$  and  $1 \leq j \leq k_2$ . In this case, one may also apply the non-anticipating Itô formula to

$$\begin{cases} a_i(t + s_{1,1}, X(t + s_{1,1})) - a_i(t_0 + s_{1,1}, X(t_0 + s_{1,1})) \\ a_i(t + s_{1,1}, X(t + s_{1,1})) - a_i(t_0 + s_{1,1}, X(t_0 + s_{1,1})) \end{cases}$$

to prove Theorem 5.2 (cf. [32]).

(ii) One can allow the initial process  $\eta$  to be a sample continuous semimartingale in the following way. Replace  $W$  by an extended Brownian motion  $W(t), t \geq -\tau$ , with the associated Brownian filtration  $(\mathcal{F}_t)_{-\tau \leq t \leq a}$ . Assume that  $\eta(t) \in \mathbb{D}_m^{1,\infty}$  for all  $t \in [-\tau, 0]$ , and  $\eta$  is an  $(\mathcal{F}_t)_{-\tau \leq t \leq 0}$ -continuous semimartingale satisfying

$$(5.23) \quad \sup_{-\tau \leq \alpha < \beta \leq 0} E|\eta(\beta) - \eta(\alpha)|^2 \leq C_2|\beta - \alpha|^\gamma, \quad \sup_{-\tau \leq s \leq 0} E(|Z^\pi(s)|^2) \leq C'|\pi|^{2\gamma}$$

for some positive constants  $C_2$  and  $C'$ . The arguments in Section 2 and the proof of Theorem 5.2 may be adapted to include this generalization.

We can rewrite the SDDE (1.6) in Stratonovich form, namely, if  $t \geq 0$ ,

$$(5.24) \quad \begin{aligned} X(t) = & \eta(0) + \int_0^t g(s, \Pi_1(X_s)) \circ dW(s) \\ & + \int_0^t \left[ h(s, \Pi_2(X_s)) - \frac{1}{2} \frac{\partial g}{\partial x_{k_1}}(s, \Pi_1(X_s)) g(s, \Pi_1(X_s)) \right] ds, \end{aligned}$$

if  $s_{k_1} = 0$ . If  $s_{k_1} < 0$ , then the SDDE is of the same form as (1.6) except the Itô integral is replaced by Stratonovich integral, i.e.,

$$X(t) = \eta(0) + \int_0^t g(s, \Pi_1(X_s)) \circ dW(s) + \int_0^t h(s, \Pi_2(X_s)) ds,$$

Bell and Mohammed ([6]) derived a similar result in the case of a single delay. From Corollary 2.8, we can obtain the following Stratonovich-Taylor expansion of  $X(t)$  (cf. [32]):

(5.25)

$$\begin{aligned} X(t) &= X(t_0) + g(t_0, \Pi_1(X_{t_0}))[W(t) - W(t_0)] + \bar{h}(t_0, \Pi_2(X_{t_0}))(t - t_0) \\ &+ \sum_{i=1}^{k_1} \frac{\partial g}{\partial x_i}(t_0, \Pi_1(X_{t_0}))u(t_0 + s_{1,i}) \int_{t_0}^t \int_{t_0+s_{1,i}}^{t_1+s_{1,i}} \circ dW(t_2) \circ dW(t_1) + \bar{R}(t_0, t), \end{aligned}$$

where

$$\begin{aligned} (5.26) \quad \bar{R}(t_0, t) &= \sum_{i=1}^{k_1} \left\{ \int_{t_0}^t \int_{t_0+s_{1,i}}^{t_1+s_{1,i}} \left[ \frac{\partial g}{\partial x_i}(t_2 - s_{1,i}, \Pi_1(X_{t_2-s_{1,i}}))u(t_2) \right. \right. \\ &- \left. \left. \frac{\partial g}{\partial x_i}(t_0, \Pi_1(X_{t_0}))u(t_0 + s_{1,i}) \right] \circ dW(t_2) \circ dW(t_1) \right\} \\ &+ \int_{t_0}^t \int_{t_0}^{t_1} \sum_{i=1}^{k_1} \frac{\partial g}{\partial x_i}(t_2, \Pi_1(X_{t_2}))\bar{v}(t_2 + s_{1,i}) dt_2 \circ dW(t_1) \\ &+ \sum_{i=1}^{k_2} \int_{t_0}^t \int_{t_0+s_{2,i}}^{t_1+s_{2,i}} \frac{\partial \bar{h}}{\partial \bar{x}_i}(t_2 - s_{2,i}, \Pi_2(X_{t_2-s_{2,i}}))u(t_2) \circ dW(t_2) dt_1 \\ &+ \int_{t_0}^t \int_{t_0}^{t_1} \sum_{i=1}^{k_2} \frac{\partial \bar{h}}{\partial \bar{x}_i}(t_2, \Pi_2(X_{t_2}))\bar{v}(t_2 + s_{2,i}) dt_2 dt_1. \end{aligned}$$

and

$$(5.27) \quad \bar{h} = h - \frac{1}{2}g_{k_1}g, \text{ and } \bar{v}(t) = \begin{cases} \bar{h}(t, \Pi_2(X_t)), & 0 \leq t \leq a \\ \eta(t), & t < 0. \end{cases}$$

One can also derive the Milstein scheme for (5.24) using the Stratonovich-Taylor expansion (5.25) of  $X(t)$  as follows: Let  $t_k < t \leq t_{k+1}$ . Then

(5.28)

$$\begin{aligned} X^\pi(t) &= X^\pi(t_k) + \bar{h}(t_k, \Pi_2(X_{t_k}^\pi))(t - t_k) + g(t_k, \Pi_1(X_{t_k}^\pi))(W(t) - W(t_k)) \\ &+ \sum_{i=1}^{k_1} \frac{\partial g}{\partial x_i}(t_k, \Pi_1(X_{t_k}^\pi))u^\pi(t_k + s_{1,i})J(t_k + s_{1,i}, t + s_{1,i}; s_{1,i}), \end{aligned}$$

where

$$u^\pi(t) = \begin{cases} g(t, \Pi_1(X_t^\pi)), & t \geq 0, \\ 0, & -\tau \leq t < 0. \end{cases}$$

### 5.3. The multidimensional Milstein scheme.

Write  $h(s, x) = (h^1(s, x), \dots, h^m(s, x))^T$ ,  $\vec{x} \in \mathbf{R}^{mk_1}$ ,

$$\vec{x} = \begin{pmatrix} x_{11}, \dots, x_{1k_1} \\ \dots \\ x_{m1}, \dots, x_{mk_1} \end{pmatrix}.$$

Denote by  $g^{jl}(s, \vec{x})$  the  $(j, l)$  element of the  $m \times d$  matrix  $g(s, \vec{x})$ . To simplify notation, we use below the summation convention on repeated indices. Recall the notations for the partition  $-\tau = t_{-y} < \dots < t_0 = 0 < \dots < t_n = t$  introduced in Section 2. We formulate the *Milstein* scheme for the SDDE (1.6) as follows: if  $t_k < t \leq t_{k+1}$ , the  $i$ th coordinate  $X^i(t)$  of  $X(t) = (X^1(t), \dots, X^m(t))^T$  is approximated by

$$(5.29) \quad \begin{aligned} X^{i,\pi}(t) &= X^{i,\pi}(t_k) + h^i(t_k, \Pi_2(X_{t_k}^\pi))(t - t_k) + g^{ij}(t_k, \Pi_1(X_{t_k}^\pi))(W^j(t) - W^j(t_k)) \\ &\quad + \frac{\partial g^{ij}}{\partial x_{i_1 j_1}}(t_k, \Pi_1(X_{t_k}^\pi)) u^{i_1 j_1, \pi}(t_k + s_{1, j_1}) I_{j, j_1}(t_k + s_{1, j_1}, t + s_{1, j_1}; s_{1, j_1}), \end{aligned}$$

where

$$u^{i_1 j_1, \pi}(t) = \begin{cases} g^{i_1 j_1}(t, \Pi_1(X_t^\pi)), & t \geq 0, \\ 0, & -\tau \leq t < 0. \end{cases}$$

As in the SODE case ([17], [18]) and in view of Lemma (4.2), it is possible to further discretize the double stochastic integral  $I_{j, j_1}(t_k + s_{1, j_1}, t + s_{1, j_1}; s_{1, j_1})$  in (5.29) to obtain a modified Milstein scheme for the SDDE (1.6) with strong order of convergence 1. More details are given in Appendix (B).

*Remark 5.4.*

One may check that Lemma 5.1, Theorems 5.2 also hold in the multidimensional case. In fact, it is easy to extend these results to the multidimensional case, thanks to the weak differentiability results (Proposition 3.1, Lemma 3.2 and Proposition 3.3) and the

results concerning strong approximation of double Stratonovich integrals (Lemma 4.1 and Lemma 4.2).

Unlike the SODE case, it seems very difficult to develop higher order strong approximation schemes for the SDDE (1.6). One may try to avoid involving the *differential operator*  $D$  and the *trace operator*  $\nabla$  in the numerical scheme by attempting to employ multiple Stratonovich integrals instead of multiple Skorohod integrals. The idea is to use Stratonovich-Taylor expansions of the coefficients in the SDDE (1.6) (c.f. (5.3) and (5.4)) instead of Itô-Taylor expansions. However, this is difficult, because it is hard to estimate the order of the error via the remainder term. This is because a multiple (anticipating) Stratonovich integral can not be expressed in terms of multiple (non-anticipating) Itô integrals. The *Hu-Meyer Formula* gives the relationship between multiple Stratonovich and Skorohod integrals ([9], Theorem 3.1 (with non-deterministic kernels); [33], Theorem 3.1 and [31], Theorem 3.4 (with deterministic kernels)) (c.f. [28], [33] and [31]). However, the formula still involves the differential operator  $D$  and the trace operator  $\nabla$ , and hence it is hard to estimate the remainder term.

One may refer to Jolis and Sanz ([17]), Delgado and Sanz ([9]), Solé and Utzet ([31]), and Zakai ([33]) for multiple Skorohod and multiple Stratonovich integrals.

## Appendix A.

The lemma below follows from the independent increments property of Brownian motion. It will be needed in the proof of the Itô formula for tame functions (Theorem 2.3).

### Lemma A.0.

Assume that  $\{\pi_n : 0 = t_0 < t_1 < \dots < t_n = a\}$  is a family of partitions of  $[0, a]$ , with  $\lim_{n \rightarrow \infty} |\pi_n| = 0$ . Let  $-\tau \leq s_1 \leq s_2 \leq 0$  and denote by  $\Delta_{lk} W^i := W^i(t_l + s_k) - W^i(t_{l-1} + s_k)$ ,  $1 \leq i \leq d, 1 \leq l \leq n, k = 1, 2$ , the increments of Brownian motion. Then

$$(A.0) \quad \lim_{n \rightarrow \infty} \sum_{l=1}^n \Delta_{l1} W^i \Delta_{l2} W^j = \begin{cases} a + s_1, & \text{if } i = j \text{ and } s_1 = s_2 \\ 0, & \text{otherwise,} \end{cases}$$

in  $L^2(\Omega, \mathbf{R})$ .

*Proof.*

We only need to consider the case  $s_1 < s_2$  and  $i = j$ . Now

$$\left[ \sum_{l=1}^n \Delta_{l1} W^i \Delta_{l2} W^i \right]^2 = \sum_{l=1}^n (\Delta_{l1} W^i)^2 (\Delta_{l2} W^i)^2 + 2 \sum_{l_1 < l_2} \Delta_{l_1 1} W^i \Delta_{l_1 2} W^i \Delta_{l_2 1} W^i \Delta_{l_2 2} W^i.$$

If  $n$  is sufficiently large, then  $|\pi_n| < s_2 - s_1$ . Hence  $\Delta_{l_2 2} W^i$  is independent of  $\Delta_{l_1 1} W^i \Delta_{l_1 2} W^i \Delta_{l_2 1} W^i$ . Taking expectations in the above equality gives

$$E \left[ \sum_{l=1}^n \Delta_{l1} W^i \Delta_{l2} W^i \right]^2 \leq \sum_{l=1}^n (t_l - t_{l-1})^2 \leq |\pi_n| a.$$

for sufficiently large  $n$ . Note that  $a + s_1$  is the correct limit in (2.6) because of the convention that  $W(t) = 0$  for  $t < 0$ . This completes the proof of the lemma.  $\square$

The following lemma extends a result by Nualart and Pardoux ([24], Lemma C1).

**Lemma A.1.**

*Suppose that  $x = \{x(t) : t \in [0, a]\}$  is a measurable real-valued process,  $x(t) = 0$  if  $t > a$  or  $t < 0$ , and  $x \in L^p([0, a], \mathbf{R})$  a.s.,  $p > 1$ . Assume that  $\{\pi_n : 0 = t_0 < t_1 < \dots < t_n = a\}$  is a family of partitions of  $[0, a]$ , with  $\lim_{n \rightarrow \infty} |\pi_n| = 0$ , and  $-\tau \leq s_1, s_2 \leq 0$ . Then*

$$(A.1) \quad \lim_{n \rightarrow \infty} \sum_{l=1}^n \frac{\Delta_{l1} W \Delta_{l2} W}{t_l - t_{l-1}} \int_{t_{l-1} + s_1}^{t_l + s_1} x(s) ds = \begin{cases} \int_0^{a+s_1} x(s) ds, & s_1 = s_2 \\ 0, & s_1 \neq s_2 \end{cases}$$

*in probability. Moreover, if  $x \in L^p(\Omega \times [0, a], \mathbf{R})$ , then the above convergences hold in  $L^1(\Omega, \mathbf{R})$ .*

*Proof.*

It clearly suffices to show that (A.1) holds in  $L^1(\Omega, \mathbf{R})$  whenever  $x \in L^p(\Omega \times [0, a], \mathbf{R})$ . Fix  $m \geq 1$ , define

$$x^m = \sum_{l=1}^m \frac{I_{(t_{l-1} + s_1, t_l + s_1]}}{t_l - t_{l-1}} \int_{t_{l-1} + s_1}^{t_l + s_1} x(s) ds.$$

For  $n \geq 1$ , define

$$\alpha_n(x) = \sum_{l=1}^n \frac{\Delta_{l1} W \Delta_{l2} W}{t_l - t_{l-1}} \int_{t_{l-1}+s_1}^{t_l+s_1} x(s) ds.$$

Define  $\alpha_n(X_m)$  similarly. It follows from Hölder's inequality that if  $1/p + 1/q = 1$ , then

$$(A.2) \quad E|\alpha_n(x)| \leq \left\{ E \sum_{l=1}^n \frac{|\Delta_{l1} W \Delta_{l2} W|^q}{(t_l - t_{l-1})^{q-1}} \right\}^{\frac{1}{q}} \left\{ E \sum_{l=1}^n \frac{(\int_{t_{l-1}+s_1}^{t_l+s_1} |x(s)| ds)^p}{(t_l - t_{l-1})^{\frac{p}{q}}} \right\}^{\frac{1}{p}},$$

i.e.

$$\|\alpha_n(x)\|_{L^1(\Omega)} \leq C_p \|x\|_{L^p(\Omega \times [0, a+s_1])} \leq C_p \|x\|_{L^p(\Omega \times [0, a])},$$

Therefore,

$$(A.3) \quad \begin{aligned} E|\alpha_n(x) - \int_0^{a+s_1} x(s) ds| &\leq E|\alpha_n(x - x^m)| + E|\alpha_n(x^m) - \int_0^{a+s_1} x(s) ds| \\ &\leq E|\alpha_n(x^m) - \int_0^{a+s_1} x(s) ds| + C_p \|x - x^m\|_{L^p(\Omega \times [0, a+s_1])}, \end{aligned}$$

since

$$\begin{aligned} \alpha_n(x^m) &= \sum_{i=1}^m \left\{ \sum_{\substack{(t_{l-1}, t_l] \subseteq (t_{i-1}, t_i] \\ 1 \leq l \leq n}} \int_{t_{i-1}+s_1}^{t_i+s_1} \frac{I_{(t_{i-1}+s_1, t_i+s_1]}(t)}{t_l - t_{l-1}} dt \Delta_{l1} W \Delta_{l2} W \right\} \\ &\quad \times \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}+s_1}^{t_i+s_1} x(s) ds \\ &= \sum_{i=1}^m \left\{ \sum_{\substack{(t_{l-1}, t_l] \subseteq (t_{i-1}, t_i] \\ 1 \leq l \leq n}} \Delta_{l1} W \Delta_{l2} W \right\} \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}+s_1}^{t_i+s_1} x(s) ds. \end{aligned}$$

Let  $k_m$  be the index such that  $t_{k_m-1} + s_1 < 0 \leq t_{k_m} + s_1$ . If  $s_1 = s_2$ , then by Lemma 2.2,

the following limit exists in probability

$$\begin{aligned} \lim_{n \rightarrow \infty} \alpha_n(x^m) &= \sum_{i=1}^m [(t_i + s_1) \wedge 0 - (t_{i-1} + s_1) \vee 0] \frac{1}{t_i - t_{i-1}} \int_{t_{i-1}+s_1}^{t_i+s_1} x(s) ds \\ &= \sum_{i=k_m+1}^m \int_{t_{i-1}+s_1}^{t_i+s_1} x(s) ds + \frac{t_{k_m} + s_1}{t_{k_m} - t_{k_m-1}} \int_0^{t_{k_m}+s_1} x(s) ds \\ &= \int_0^{a+s_1} x(s) ds + \frac{t_{k_m} + s_1}{t_{k_m} - t_{k_m-1}} \int_0^{t_{k_m}+s_1} x(s) ds. \end{aligned}$$

Equivalently,

$$\alpha_n(x^m) - \int_0^{a+s_1} x(s) ds - \frac{t_{k_m} + s_1}{t_{k_m} - t_{k_m-1}} \int_0^{t_{k_m} + s_1} x(s) ds \rightarrow 0$$

as  $n \rightarrow \infty$  in probability.

A slight modification in the proof of (A.2) yields the estimate

$$\|\alpha_n(x^m)\|_{L^{p'}(\Omega)} \leq C(p, p') \|x^m\|_{L^p(\Omega \times [0, a+s_1])},$$

for all  $p' \in (1, p)$ . Therefore, the family  $\{\alpha_n(x^m) : n \geq 1\}$  is uniformly integrable. From (A.3) we have

$$\begin{aligned} \lim_{n \rightarrow \infty} E |\alpha_n(x) - \int_0^{a+s_1} x(s) ds| \\ \leq E \left| \frac{t_{k_m} + s_1}{t_{k_m} - t_{k_m-1}} \int_0^{t_{k_m} + s_1} x(s) ds \right| + C_p \|x - x^m\|_{L^p(\Omega \times [0, a+s_1])} \\ \leq E \int_0^{t_{k_m} + s_1} |x(s)| ds + C_p \|x - x^m\|_{L^p(\Omega \times [0, a+s_1])}. \end{aligned}$$

Clearly,  $x^m \rightarrow x$  in  $L^p(\Omega \times [0, a+s_1])$  and  $E \int_0^{t_{k_m} + s_1} |x(s)| ds \rightarrow 0$  as  $m \rightarrow \infty$ . So

$$\lim_{n \rightarrow \infty} E |\alpha_n(x^m) - \int_0^{a+s_1} x(s) ds| = 0.$$

Now consider the case  $s_1 \neq s_2$ . Since

$$\begin{aligned} E |\alpha_n(x)| &\leq E |\alpha_n(x^m)| + E |\alpha_n(x - x^m)| \\ &\leq E |\alpha_n(x^m)| + C_p \|x - x^m\|_{L^p(\Omega \times [0, a+s_1])}. \end{aligned}$$

A similar argument gives  $\lim_{n \rightarrow \infty} E |\alpha_n(x)| = 0$ .  $\square$

The following useful result is due to Föllmer ([10]), and Nualart and Pardoux ([24], Lemma C.2):

**Lemma A.2.**

Let  $x^i(t), 0 \leq t \leq a, i = 1, 2$ , be two continuous processes, and  $\{\pi_n : 0 = t_0 < t_1 < \dots < t_n = a\}$  a family of partitions of  $[0, a]$ , with  $\lim_{n \rightarrow \infty} |\pi_n| = 0$ . For each  $n$  and  $l = 1, \dots, n$ , let  $x_{t_l, n}^i$  denote  $x^i(t_l)$ . Assume that

$$(A.4) \quad \sum_{l=1}^n (x_{t_l, n}^i - x_{t_{l-1}, n}^i)(x_{t_l, n}^j - x_{t_{l-1}, n}^j) \rightarrow \int_0^a a^{ij}(s) ds$$

in probability as  $n \rightarrow \infty$ , where  $\{a^{ij}(t) : 0 \leq t \leq a; i, j = 1, 2\}$  are measurable processes such that a.s.

$$(A.5) \quad \int_0^a |a^{ij}(s)| ds < \infty, \quad i, j = 1, 2.$$

Let  $\{Y(t) : 0 \leq t \leq a\}$  be a continuous process, and  $\{Y^n(t) : 0 \leq t \leq a\}_{n=1}^\infty$  be measurable processes which converge a.s. to  $\{Y(t)\}$  as  $n \rightarrow \infty$ , uniformly with respect to  $t \in [0, a]$ .

Then

$$(A.6) \quad \sum_{l=1}^n Y^n(t_{l-1})(x_{t_l, n}^i - x_{t_{l-1}, n}^i)(x_{t_l, n}^j - x_{t_{l-1}, n}^j) \rightarrow \int_0^a a^{ij}(s)Y(s) ds$$

in probability as  $n \rightarrow \infty$ , for  $i = 1, 2$ .

**Appendix B. Simulating a double stochastic integral.**

The following scheme is adapted from Kloeden and Platen ([18], p. 202; [19], p. 82).

In view of Lemma 4.2, we can use the truncated sums

$$(B.1) \quad \begin{aligned} J_{i,j}^p(0, t; -b) &= \frac{1}{2}(W^i(t)B^j(t)) - \frac{1}{2}(W^i(t)a_0^{j,b} - B^j(t)a_0^i) \\ &\quad + \pi \sum_{n=1}^p n(a_n^i b_n^{j,b} - b_n^i a_n^{j,b}), \quad t \geq 0, p \geq 1, \end{aligned}$$

to simulate the double Stratonovich integral

$$(B.2) \quad J_{i,j}(0, t; -b) = \int_b^{t+b} \int_0^{s-b} \circ dW^i(v) \circ dW^j(s).$$

Consider the Milstein scheme (5.9). Given an error bound  $\delta = O(|\pi|^2)$ , we choose an integer  $p \geq 1$  such that

$$\frac{1}{p} \leq \delta \wedge \min\{|s_{1,i}| : 1 \leq i \leq k_1\}.$$

We define for all such integers  $p$ ,

$$(B.3) \quad I^p(t_k + s_{1,i}, t + s_{1,i}; s_{1,i}) := \begin{cases} J_{ij}^p(t_k + s_{1,i}, t + s_{1,i}; s_{1,i}), & s_{1,i} < 0 \\ \frac{(W(t) - W(t_0))^2}{2} - \frac{t - t_0}{2}, & s_{1,i} = 0. \end{cases}$$

By Lemma (4.2), the following modification of the Milstein scheme

$$(B.4) \quad \begin{aligned} X^\pi(t) = & X^\pi(t_k) + h(t_k, \Pi_2(X_{t_k}^\pi))(t - t_k) + g(t_k, \Pi_1(X_{t_k}^\pi))(W(t) - W(t_k)) \\ & + \sum_{i=1}^{k_1} \frac{\partial g}{\partial x_i}(t_k, \Pi_1(X_{t_k}^\pi)) u^\pi(t_k + s_{1,i}) I^p(t_k + s_{1,i}, t + s_{1,i}; s_{1,i}), \quad t_k < t \leq t_{k+1}, \end{aligned}$$

has strong order of convergence 1 (c.f. Theorem 5.2).

Suppose that we use the family of partitions:  $\pi : -1 = t_{-l} < \dots < t_0 = 0 < \dots < t_n = a$ , mesh  $\pi = |\pi|$ , to calculate the solution of the SDDE (1.6) by applying Milstein scheme. There are some issues we need to consider concerning simulating the family

$$S = \{J(t_{k-1}, t_k; s_{1,i}) : k = 1, \dots, n, i = 1, \dots, k_1\}.$$

If  $k_1 \neq k_2$  or  $i_1 \neq i_2$ , by the Itô isometry,  $J(t_{k_1-1}, t_{k_1}; s_{1,i_1})$  and  $J(t_{k_2-1}, t_{k_2}; s_{1,i_2})$  are independent. But the family  $S$  may not be independent. The reason is that they come from the same Brownian motion. We can make  $S$  independent by choosing appropriate mesh points so that  $t_k + s_{1,i} \in \pi$ , for all  $k \geq 0, 1 \leq i \leq k_1$ , i.e.,  $t_k + s_{1,i}$  is also a mesh point. In order to see this, set

$$(B.5) \quad V_k = \{(a_n(t_{k-1}), b_n(t_{k-1})) : n = 0, 1, \dots\},$$

where  $a_n(t_{k-1})$  and  $b_n(t_{k-1})$  are defined by (4.6). Then for all  $1 \leq i \leq k_1, 1 \leq k \leq n$ , the set

$$(B.6) \quad V_k(s_{1,i}) = \{(a_n^{-s_{1,i}}(t_{k-1}), b_n^{-s_{1,i}}(t_{k-1})) : n = 0, 1, \dots\}$$

belongs to the family  $\{V_k : k = 1, \dots, n\}$ , where  $a_n^{-s_{1,i}}(t_{k-1})$  and  $b_n^{-s_{1,i}}(t_{k-1})$  are defined by (4.7). Indeed, similar to the approximation scheme of multiple Stratonovich integrals ([18], (5.8.10) and (5.8.12); [19], (2.3.30) and (2.3.32)), we have the following approximation scheme of  $\{J^p(t_{k-1}, t_k; s_{1,i}) : k = 1, \dots, n, i = 1, \dots, k_1\}$ ,  $p \geq 1$ .

For each  $k = 1, \dots, n$ , and  $h = 1, \dots, p$ , with  $p \geq 1$ , we define  $\rho_p$  and independent  $N(0, 1)$  random variables  $\xi(s)$ ,  $\mu_p(s)$ ,  $\zeta_h(s)$ ,  $\eta_h(s)$ ,  $s \in \{t_0, \dots, t_{n-1}\}$ , by

$$(B.7) \quad \begin{aligned} \xi(s) &= \frac{1}{|\pi|} (W(|\pi| + s) - W(s)), \\ \zeta_h(s) &= \sqrt{\frac{2}{|\pi|}} h \pi a_h(s), \quad \eta_h(s) = \sqrt{\frac{2}{|\pi|}} h \pi b_h(s), \\ \rho_p &= \frac{1}{12} - \frac{1}{2\pi^2} \sum_{h=1}^p \frac{1}{h^2}, \quad \mu_p(s) = \frac{1}{\sqrt{|\pi|\rho_p}} \sum_{h=p+1}^{\infty} a_h(s), \\ a_0(s) &= -\frac{1}{\pi} \sqrt{2|\pi|} \sum_{h=1}^p \frac{1}{h} \zeta_h(s) - 2\sqrt{|\pi|\rho_p} \mu_p(s). \end{aligned}$$

If  $t_{k-1} + s_{1,i} \geq 0$ , then

$$(B.8) \quad \begin{aligned} &J^p(t_{k-1} + s_{1,i}, t_k + s_{1,i}; s_{1,i}) \\ &= \frac{1}{2} |\pi| [\xi(t_{k-1} + s_{1,i}) \xi(t_{k-1}) - \frac{1}{2} \sqrt{|\pi|} [\xi(t_{k-1} + s_{1,i}) a_0(t_{k-1}) - \xi(t_{k-1}) a_0(t_{k-1} + s_{1,i})]] \\ &\quad + \frac{|\pi|}{2\pi} \sum_{h=1}^p \frac{1}{h} [\zeta_h(t_{k-1} + s_{1,i}) \eta_h(t_{k-1}) - \zeta_h(t_{k-1}) \eta_h(t_{k-1} + s_{1,i})]. \end{aligned}$$

*Remarks B.1.*

- (i) The space complexity of the Milstein scheme for SDDE is  $O(ma/|\pi|)$  if we only want to simulate the end point  $X(a)$  (or the end segment  $X_a$ ). The space complexity of the Milstein scheme for an m-dimensional SODE is  $O(ma)$  if we only want to simulate the end point  $X(a)$ . If we want to simulate the whole path  $\{X(t) : t \in [0, a]\}$ , then both schemes have the same space complexity  $O(ma/|\pi|)$ .
- (ii) Roughly speaking, the time complexity of the Milstein scheme for a multidimensional SDDE ( $m > 1$ ) is  $K$  times the time complexity of the corresponding scheme

for an SODE, where  $K := k_1 + k_2$  is the total number of delays. If  $m = 1$ , we can directly simulate the double stochastic integral in the Milstein scheme using (B.3).

- (iii) In view of (B.7) and (B.8), we do not need to simulate the joint law of multi-variate normal variables for multidimensional SDDE's and SODE's. If  $m$  is not very large, simulating the joint law is not a prohibitive task by using Cholesky's decomposition.

### **Acknowledgement.**

The authors are very grateful to the anonymous referees and to the editors of the *Annals of Probability* for their helpful suggestions and comments on an earlier version of the manuscript.
